On some estimations of the trigonometrical sums

in an algebraic number field

Y. Eda (Nagoya)

§ 1   Introduction

We have discussed the Waring Problem in an algebraic number field[1] as an application of Vinogradov's mean value theorem [2].   This is another application of our previous paper [2].   Using the Korobov's method we shall prov⌄e the estimations of some trigonometrical sums in minor arcs in an algebraic number field.[3] Our results will be given as Theorem 1 and Theorem 2 in §3.   In the rational number field the estimations of this type are very interesting and important in the analytic theory of numbers. We use a letter c to denote a positive constant depending on K alone. It is not necessarily the same one each time it occurs.   The constant c may well depend on another parameter *.   In this case we write as c(*) to explain the meaning.   We use the same terminology and notations as before.[1,2]

§ 2 Lemmata

Let $\underline{\lambda} = (\lambda_o, \lambda_1, \ldots, \lambda_{k-1})$ and $\underline{\alpha} = (\alpha_0, \alpha_1, \ldots, \alpha_{k-1})$ be k+2 dimensional complex row vectors and let $\underline{\mu}^* = (\mu_0, \mu_1, \ldots, \mu_{k+1})^*$ be a k+2 dimensional complex colum vector (we call $\underline{\mu}^*$ the transposed of $\underline{\mu}$).   Further let A be a k+2 dimensional quadratic (symmetric)

1

matrix such that

$$A = \begin{bmatrix} \binom{0}{0}\alpha_0, & \binom{1}{1}\alpha_1, & \cdots, & \binom{k}{k}\alpha_k, & \binom{k+1}{k+1}\alpha_{k+1} \\ \binom{1}{0}\alpha_1, & \binom{2}{1}\alpha_2, & \cdots, & \binom{k+1}{k}\alpha_{k+1}, & 0 \\ & \cdots\cdots\cdots\cdots \\ \binom{k}{0}\alpha_k, & \binom{k+1}{1}\alpha_{k+1}, & \cdots\cdots \\ \binom{k+1}{0}\alpha_{k+1}, & 0, & \cdots\cdots\cdots\cdots, & 0 \end{bmatrix}$$

where $\binom{i}{j}$ are binomial coefficients and $\binom{0}{0} = 0$. We define two $k+2$ dimensional complex vectors $\underline{\beta} = (\beta_0, \beta_1, \ldots, \beta_{k+1})$ and $\underline{\gamma}^* = (\gamma_0, \gamma_1, \ldots, \gamma_{k+1})^*$ by the following relations:

$$\underline{\lambda} A \underline{\mu} = \underline{\beta}\,\underline{\mu}^* = \underline{\lambda}\,\underline{\gamma}^*.$$

Then we have

$$\beta_i = \binom{i}{i}\alpha_i \lambda_0 + \binom{i+1}{i}\alpha_{i+1}\lambda_1 + \cdots + \binom{k+1}{i}\alpha_{k+1}\lambda_{k+1-i} \quad (0 \le i \le k+1)$$

and

$$\gamma_i = \binom{i}{0}\alpha_i \mu_0 + \binom{i+1}{1}\alpha_{i+1}\mu_1 + \cdots + \binom{k+1}{k+1-i}\alpha_{k+1}\mu_{k+1-i} \quad (0 \le i \le k+1).$$

Let $N_s(T; \nu_1, \ldots, \nu_k)$ be the number of solutions of the system of k ($k \ge 2$) diophantine equations

$$\begin{cases} \lambda_1 + \lambda_2 + \cdots + \lambda_s = \mu_1 + \mu_2 + \cdots + \mu_s + \nu_1 \\ \lambda_1^2 + \lambda_2^2 + \cdots + \lambda_s^2 = \mu_1^2 + \mu_2^2 + \cdots + \mu_s^2 + \nu_2 \\ \cdots\cdots\cdots\cdots \\ \lambda_1^k + \lambda_2^k + \cdots + \lambda_s^k = \mu_1^k + \mu_2^k + \cdots + \mu_s^k + \nu_k, \end{cases}$$

where $\vartheta \ni \lambda_j$, $\lambda_j \prec T$, $(1 \leq j \leq s)$ and $\nu_1, \ldots, \nu_k$ are arbitrarily fixed integers in ϑ. Let $N_s(T; 0, \ldots, 0) = N_s(T) = N_{s,k}(T)$.

We have now to describe two lemmas. They are essential to prove the following theorems.

Lemma 1 $\quad k \geq 2$ denotes a positive integer. R is a sufficiently large positive number. T is a positive real number with the condition that

$$(2R)^{k(1 + 1/(k-1))^{\tau - 1}} \prec T$$

with a positive integer $\tau \geq 1$. Further let s be a positive integer with

$$s \geq \frac{n}{2(n-1)} k(k+1) + \tau k - 1.$$

Then we have the following estimate:

$$N_s(T) \leq c^{(k^2 + 2s + \frac{(\tau-1)}{k}s - \frac{1}{4}(\tau-1)(k+1))\tau} \, 2k \, s^{2sn - \frac{1}{2}k(k+1)n + \mathcal{S}n},$$

where

$$\mathcal{S} = \mathcal{S}(k, \tau) = \tfrac{1}{2}k(k+1)(1 - 1/k)^{\tau}.$$

This is the Vinogradov's mean value theorem in an algebraic number field.

Lemma 2 $\quad$ Let m, m_1 be two natural numbers and let T_1, T be real numbers such that $0 < T_1 \leq T$. We define a trigonometrical sum S as follows:

$$S = S(\alpha_1, \ldots, \alpha_{k+1}) = \sum_{\lambda \prec T} E(f(\lambda))$$

where $f(\lambda) = \alpha_1 \lambda + \cdots + \alpha_{k+1} \lambda^{k+1}$ and the summation means that λ runs through all $\lambda \in \vartheta$ such that $\lambda \prec T$. Let

$$\tilde{\beta}_\nu = \binom{\nu+1}{\nu}\alpha_{\nu+1}\tilde{\lambda}_1 + \cdots + \binom{k+1}{\nu}\alpha_{k+1}\tilde{\lambda}_{k+1-\nu} \quad (1 \leq \nu \leq k).$$

Further, we write

$$V_{m,m_1} = \sum_{\substack{\tilde{\lambda}_1,\cdots,\tilde{\lambda}_k \\ \tilde{\mu}_1,\cdots,\tilde{\mu}_k}} N_m(T; \tilde{\lambda}_1,\ldots,\tilde{\lambda}_k) N_{s1}(T_1; \tilde{\mu}_1,\ldots,\tilde{\mu}_k) E(\tilde{\beta}_1\tilde{\mu}_1 + \ldots + \tilde{\beta}_k\tilde{\mu}_k)$$

where the summation means that $\tilde{\lambda}_i, \tilde{\mu}_i$ ($1 \leqq i \leqq k$) run through all

$\tilde{\lambda}_i, \tilde{\mu}_i \in \mathcal{19}$ such that

$$\left| \lambda_\nu^{(p)} \right| < mT^\nu, \quad \left| \mu_\nu^{(p)} \right| \leqq m_1 T_1^\nu \quad (1 \leqq p \leqq n_1),$$

$$\left| \lambda_\nu^{(q)} \right| \quad 2mT^\nu, \quad \left| \mu_\nu^{(q)} \right| \leqq 2m_1 T_1^\nu \quad (n_1+1 \leqq q \leqq n_1+n_2)(1\leqq \nu \leqq k).$$

Then we have

$$\left| \tfrac{1}{2}S \right|^{4mm_1} \leqq T^{4m_1mn} T^{-2mn} T_1^{-2m_1n} V_{mm_1} + (c\, T_1 T^{n-1})^{4mm_1}.$$

This is fundamental lemma of Korobov in an algebraic number field.

§3 Theorems

Theorem 1.   Let T be a sufficiently large number and $k \geqq 2$ be a positive integer.   We may suppose that $k^{\frac{1}{2}}\log k < r < k - k^{\frac{1}{2}}\log k$ and we define $\bar{s}$ and $s = \underline{s}$ by $\bar{s} = \text{Max}(k-r, r)$ and $s = \underline{s} = \text{Min}(k-r, r)$. Let $f(u) = \alpha_1 u + \alpha_2 u^2 + \ldots + \alpha_{k+1} u^{k+1}$, $\alpha_i = x_{i1}\beta_1 + \ldots + x_{in}\beta_n$, ($x_{i1},\ldots, x_{in}) \in U$, ($1 \leqq i \leqq k+1$). We put a number α_{k+1} of $E(h,t)$ which is defined by the Farey division with respect to (h,t), where $h = c^n mk^{\bar{s}} D^2 T^{\bar{s}}$, $c \geqq 32$, $m = [s^2 \log 2e^2 n]$ and $t = T^{\underline{s}}$. Then we have

$$\left| S \right| \leqq c\, T^{n - \dfrac{1}{96(\log n + 3)^2 k^2 \log k}},$$

where c is a suitable positive constant depending only on K.

4

Theorem 2 Let ε be a positive number and assume that $\varepsilon n < r <$

$(1 - \varepsilon)n$ $(0 < \varepsilon < 1)$ in theorem 1. Then we have

$$\left| S \right| \leq c(\varepsilon, n)\, T^{n - \frac{c(\varepsilon, n)}{k^2}}$$

where

$$c(\varepsilon, n) = 1/(32\log(2e^2 n)\, \log(2e^2 n/ \varepsilon^2)).$$

To obtain these results we must use some results of Siegel and Mitsui of

the estimations of trigonometrical sums in an algebraic number field $(4,5,6)$.
