Non-Commutative Geometry and the Local Langlands Conjecture

Paul Frank Baum

(The Pennsylvania State University)

Abstract

Let G be a reductive p-adic group. Examples are $GL(n, F)$, $SL(n, F)$, etc where n can be any positive integer and F can be any finite extension of the field Q_p of p-adic numbers. The smooth dual of G is the set of (equivalence classes of) smooth representations of G. The representations are on vector spaces over the complex numbers. In a canonical way, the smooth dual of G is the disjoint union of countably many subsets known as the Bernstein components.

Results from non-commutative geometry—e.g. BC (Baum–Connes) conjecture, periodic cyclic homology of the Hecke algebra of G—indicate that a very simple geometric structure might be present in the smooth dual of G. The ABP (Aubert–Baum–Plymen) conjecture makes this precise by asserting that each Bernstein component in the smooth dual of G is a complex affine variety. These varieties are explicitly identified as certain extended quotients. For split G, (granted a mild restriction on the residual characteristic) the ABP conjecture has recently been proved for any Bernstein component in the principal series. A corollary is that the local Langlands conjecture is valid throughout the principal series. The above is joint work with Anne-Marie Aubert, Roger Plymen, and Maarten Solleveld.

Topics in these lectures:

#1. Review of the LL (Local Langlands) conjecture.

#2. Statement of the ABP conjecture.

#3. Outline of the proof that for any split reductive p-adic group G both ABP and LL are valid throughout the principal series of G. Class field theory, founded by Professor Teiji Takagi, is a basic point in all three topics.
