# MATRIX SUMMABILITY AND KOROVKIN TYPE APPROXIMATION THEOREM ON MODULAR SPACES 

S. KARAKUŞ and K. DEMIRCI

Abstract. In this paper, using a matrix summability method we obtain a Korovkin type approximation theorem for a sequence of positive linear operators defined on a modular space.

## 1. Introduction

Approximation theory has important applications in the theory of polynomial approximation, in various areas of functional analysis, in numerical solutions of differential and integral equations [9], [10], [11]. Most of the classical approximation operators tend to converge to the value of the function being approximated. However, at points of discontinuity, they often converge to the average of the left and right limits of the function. There are, however, some sharp exceptions such as the interpolation operator of Hermite-Fejer (see [7]). These operators do not converge at points of simple discontinuity. For such misbehavior, the matrix summability methods of Cesáro type are strong enough to correct the lack of convergence (see [8]). Using a matrix summability method some approximation results were studied in $[1,2,18,19,21]$. In this paper, using a matrix summability method we give a theorem of the Korovkin type for a sequence of positive linear operators defined on a modular space.

We now recall some basic definitions and notations used in the paper.

Let $I=[a, b]$ be a bounded interval of the real line $\mathbb{R}$ provided with the Lebesgue measure. Then, by $X(I)$ we denote the space of all real-valued measurable functions on $I$ provided with equality a.e. As usual, let $C(I)$ denote the space of all continuous real-valued functions, and $C^{\infty}(I)$ denote the space of all infinitely differentiable functions on $I$. In this case, we say that a functional $\rho: X(I) \rightarrow[0,+\infty]$ is a modular on $X(I)$ provided that the following conditions hold:
(i) $\rho(f)=0$ if and only if $f=0$ a.e. in $I$,
(ii) $\rho(-f)=\rho(f)$ for every $f \in X(I)$,
(iii) $\rho(\alpha f+\beta g) \leq \rho(f)+\rho(g)$ for every $f, g \in X(I)$ and for any $\alpha, \beta \geq 0$ with $\alpha+\beta=1$.

A modular $\rho$ is said to be $N$-quasi convex if there exists a constant $N \geq 1$ such that the inequality

$$
\rho(\alpha f+\beta g) \leq N \alpha \rho(N f)+N \beta \rho(N g)
$$

holds for every $f, g \in X(I), \alpha, \beta \geq 0$ with $\alpha+\beta=1$. In particular, if $N=1$, then $\rho$ is called convex.
A modular $\rho$ is said to be $N$-quasi semiconvex if there exists a constant $N \geq 1$ such that the inequality

$$
\rho(a f) \leq N a \rho(N f)
$$

holds for every $f \in X(I)$ and $a \in(0,1]$.
It is clear that every $N$-quasi convex modular is $N$-quasi semiconvex. We should recall that the above two concepts were introduced and discussed in details by Bardaro et. al. [6].

We now consider some appropriate vector subspaces of $X(I)$ by means of a modular $\rho$ as follows

$$
L^{\rho}(I):=\left\{f \in X(I): \lim _{\lambda \rightarrow 0^{+}} \rho(\lambda f)=0\right\}
$$

and

$$
E^{\rho}(I):=\left\{f \in L^{\rho}(I): \rho(\lambda f)<+\infty \text { for all } \lambda>0\right\} .
$$

Here, $L^{\rho}(I)$ is called the modular space generated by $\rho$ and $E^{\rho}(I)$ is called the space of the finite elements of $L^{\rho}(I)$. Observe that if $\rho$ is $N$-quasi semiconvex, then the space

$$
\{f \in X(I): \rho(\lambda f)<+\infty \text { for some } \lambda>0\}
$$

coincides with $L^{\rho}(I)$. The notions about modulars were introduced in [17] and widely discussed in $[6]$ (see also $[12,16]$ ).

Now we recall the convergence methods in modular spaces.
Let $\left\{f_{n}\right\}$ be a function sequence whose terms belong to $L^{\rho}(I)$. Then, $\left\{f_{n}\right\}$ is modularly convergent to a function $f \in L^{\rho}(I)$ iff

$$
\begin{equation*}
\lim _{n} \rho\left(\lambda_{0}\left(f_{n}-f\right)\right)=0 \quad \text { for some } \lambda_{0}>0 . \tag{1.1}
\end{equation*}
$$

Also, $\left\{f_{n}\right\}$ is $F$-norm convergent (or strongly convergent) to $f$ iff

$$
\begin{equation*}
\lim _{n} \rho\left(\lambda\left(f_{n}-f\right)\right)=0 \quad \text { for every } \lambda>0 . \tag{1.2}
\end{equation*}
$$

It is known from [16] that (1.1) and (1.2) are equivalent if and only if the modular $\rho$ satisfies the $\Delta_{2}$-condition, i.e., there exists a constant $M>0$ such that $\rho(2 f) \leq M \rho(f)$ for every $f \in X(I)$.

In this paper, we will need the following assumptions on a modular $\rho$ :

- if $\rho(f) \leq \rho(g)$ for $|f| \leq|g|$, then $\rho$ is called monotone,
- if the characteristic function $\chi_{I}$ of the interval $I$ belongs to $L^{\rho}(I), \rho$ is called finite,
- if $\rho$ is finite and, for every $\varepsilon>0, \lambda>0$, there exists $\delta>0$ such that $\rho\left(\lambda \chi_{B}\right)<\varepsilon$ for any measurable subset $B \subset I$ with $|B|<\delta$, then $\rho$ is called absolutely finite,
- if $\chi_{I} \in E^{\rho}(I)$, then $\rho$ is called strongly finite,
- $\rho$ is called absolutely continuous provided that there exists $\alpha>0$ such that, for every $f \in X(I)$ with $\rho(f)<+\infty$, the following condition holds: for every $\varepsilon>0$ there is $\delta>0$ such that $\rho\left(\alpha f \chi_{B}\right)<\varepsilon$ whenever $B$ is any measurable subset of $I$ with $|B|<\delta$.

Observe now that (see [5]) if a modular $\rho$ is monotone and finite, then we have $C(I) \subset L^{\rho}(I)$. In a similar manner, if $\rho$ is monotone and strongly finite, then $C(I) \subset E^{\rho}(I)$. Some important relations between the above properties may be found in $[4,6,14,17]$.

## 2. Korovkin Type Theorems

Let $\mathcal{A}:=\left(A^{n}\right)_{n \geq 1}, A^{n}=\left(a_{k j}^{n}\right)_{k, j \in \mathbb{N}}$ be a sequence of infinite non-negative real matrices. For a sequence of real numbers, $x=\left(x_{j}\right)_{j \in \mathbb{N}}$, the double sequence

$$
\mathcal{A} x:=\left\{(A x)_{k}^{n}: k, n \in \mathbb{N}\right\}
$$

defined by $(A x)_{k}^{n}:=\sum_{j=1}^{\infty} a_{k j}^{n} x_{j}$ is called the $\mathcal{A}$-transform of $x$ whenever the series converges for all $k$ and $n$. A sequence $x$ is said to be $\mathcal{A}$-summable to $L$ if

$$
\lim _{k \rightarrow \infty} \sum_{j=1}^{\infty} a_{k j}^{n} x_{j}=L
$$

uniformly in $n$ ([3], [20]).
If $A^{n}=A$ for a matrix $A$, then $\mathcal{A}$-summability is the ordinary matrix summability by $A$. If $a_{k j}^{n}=\frac{1}{k}$ for $n \leq j \leq k+n,(n=1,2, \ldots)$ and $a_{k j}^{n}=0$ otherwise, then $\mathcal{A}$-summability reduces to almost convergence [13].

Let $\rho$ be a monotone and finite modular on $X(I)$. Assume that $D$ is a set satisfying $C^{\infty}(I) \subset$ $D \subset L^{\rho}(I)$. We can construct such a subset $D$ since $\rho$ is monotone and finite (see [5]). Assume further that $\mathbb{T}:=\left\{T_{n}\right\}$ is a sequence of positive linear operators from $D$ into $X(I)$ for which there

Proof. We first claim that

$$
\begin{equation*}
\lim _{k \rightarrow \infty} \sum_{j=1}^{\infty} a_{k j}^{n} \rho\left(\mu\left(T_{j} g-g\right)\right)=0, \quad \text { uniformly in } n \tag{2.4}
\end{equation*}
$$

for every $g \in C(I)$ and every $\mu>0$. To see this assume that $g$ belongs to $C(I)$ and $\mu$ is any positive number. Then, there exists a constant $M>0$ such that $|g(x)| \leq M$ for every $x \in I$. Given $\varepsilon>0$, we can choose $\delta>0$ such that $|y-x|<\delta$ implies $|g(y)-g(x)|<\varepsilon$ where $y, x \in I$. It is easy to see that for all $y, x \in I$

$$
|g(y)-g(x)|<\varepsilon+\frac{2 M}{\delta^{2}}(y-x)^{2}
$$

Since $T_{j}$ is a positive linear operator, we get

$$
\begin{aligned}
\mid T_{j}(g ; & x)-g(x) \mid \\
\quad & =\left|T_{j}(g(\cdot)-g(x) ; x)+g(x)\left(T_{j}\left(e_{0}(\cdot) ; x\right)-e_{0}(x)\right)\right| \\
& \leq T_{j}(|g(\cdot)-g(x)| ; x)+|g(x)|\left|T_{j}\left(e_{0}(\cdot) ; x\right)-e_{0}(x)\right| \\
& \leq T_{j}\left(\varepsilon+\frac{2 M}{\delta^{2}}(\cdot-x)^{2} ; x\right)+M\left|T_{j}\left(e_{0}(\cdot) ; x\right)-e_{0}(x)\right| \\
& \leq \varepsilon T_{j}\left(e_{0}(\cdot) ; x\right)+\frac{2 M}{\delta^{2}} T_{j}\left((\cdot-x)^{2} ; x\right)+M\left|T_{j}\left(e_{0}(\cdot) ; x\right)-e_{0}(x)\right| \\
& \leq \varepsilon+(\varepsilon+M)\left|T_{j}\left(e_{0}(\cdot) ; x\right)-e_{0}(x)\right| \\
& \quad+\frac{2 M}{\delta^{2}}\left[T_{j}\left(e_{2}(\cdot) ; x\right)-2 e_{1}(x) T_{j}\left(e_{1}(\cdot) ; x\right)+e_{2}(x) T_{j}\left(e_{0}(\cdot) ; x\right)\right]
\end{aligned}
$$

$$
\begin{aligned}
\leq & \varepsilon+(\varepsilon+M)\left|T_{j}\left(e_{0}(\cdot) ; x\right)-e_{0}(x)\right|+\frac{2 M}{\delta^{2}}\left|T_{j}\left(e_{2}(\cdot) ; x\right)-e_{2}(x)\right| \\
& +\frac{4 M\left|e_{1}(x)\right|}{\delta^{2}}\left|T_{j}\left(e_{1}(\cdot) ; x\right)-e_{1}(x)\right|+\frac{2 M e_{2}(x)}{\delta^{2}}\left|T_{j}\left(e_{0}(\cdot) ; x\right)-e_{0}(x)\right| \\
\leq & \varepsilon+\left(\varepsilon+M+\frac{2 M c^{2}}{\delta^{2}}\right)\left|T_{j}\left(e_{0}(\cdot) ; x\right)-e_{0}(x)\right|+\frac{4 M c}{\delta^{2}}\left|T_{j}\left(e_{1}(\cdot) ; x\right)-e_{1}(x)\right| \\
& +\frac{2 M}{\delta^{2}}\left|T_{j}\left(e_{2}(\cdot) ; x\right)-e_{2}(x)\right|
\end{aligned}
$$

where $c:=\max \{|a|,|b|\}$. So, the last inequality gives, for any $\mu>0$ that

$$
\begin{aligned}
\mu\left|T_{j}(g ; x)-g(x)\right| \leq & \mu \varepsilon+\mu K\left|T_{j}\left(e_{0}(\cdot) ; x\right)-e_{0}(x)\right| \\
& +\mu K\left|T_{j}\left(e_{1}(\cdot) ; x\right)-e_{1}(x)\right|+\mu K\left|T_{j}\left(e_{2}(\cdot) ; x\right)-e_{2}(x)\right|
\end{aligned}
$$

where $K:=\max \left\{\varepsilon+M+\frac{2 M c^{2}}{\delta^{2}}, \frac{4 M c}{\delta^{2}}, \frac{2 M}{\delta^{2}}\right\}$. Applying the modular $\rho$ in the both-sides of the above inequality, since $\rho$ is monotone, we have

$$
\begin{aligned}
\rho\left(\mu \left(T_{j}(g ; \cdot)\right.\right. & -g(\cdot))) \\
& \leq \rho\left(\mu \varepsilon+\mu K\left|T_{j} e_{0}-e_{0}\right|+\mu K\left|T_{j} e_{1}-e_{1}\right|+\mu K\left|T_{j} e_{2}-e_{2}\right|\right) .
\end{aligned}
$$

So, we may write that

$$
\begin{aligned}
\rho\left(\mu\left(T_{j}(g ; \cdot)-g(\cdot)\right)\right) \leq & \rho(4 \mu \varepsilon)+\rho\left(4 \mu K\left(T_{j} e_{0}-e_{0}\right)\right) \\
& +\rho\left(4 \mu K\left(T_{j} e_{1}-e_{1}\right)\right)+\rho\left(4 \mu K\left(T_{j} e_{2}-e_{2}\right)\right) .
\end{aligned}
$$

Since $\rho$ is $N$-quasi semiconvex and strongly finite, we have, assuming $0<\varepsilon \leq 1$

$$
\begin{aligned}
\rho\left(\mu\left(T_{j}(g ; \cdot)-g(\cdot)\right)\right) \leq & N \varepsilon \rho(4 \mu N)+\rho\left(4 \mu K\left(T_{j} e_{0}-e_{0}\right)\right) \\
& +\rho\left(4 \mu K\left(T_{j} e_{1}-e_{1}\right)\right)+\rho\left(4 \mu K\left(T_{j} e_{2}-e_{2}\right)\right) .
\end{aligned}
$$

Hence

$$
\begin{align*}
\sum_{j=1}^{\infty} a_{k j}^{n} \rho\left(\mu\left(T_{j}(g ; \cdot)-g(\cdot)\right)\right) & \leq N \varepsilon \rho(4 \mu N) \sum_{j=1}^{\infty} a_{k j}^{n}+\sum_{j=1}^{\infty} a_{k j}^{n} \rho\left(4 \mu K\left(T_{j} e_{0}-e_{0}\right)\right)  \tag{2.5}\\
& +\sum_{j=1}^{\infty} a_{k j}^{n} \rho\left(4 \mu K\left(T_{j} e_{1}-e_{1}\right)\right)+\sum_{j=1}^{\infty} a_{k j}^{n} \rho\left(4 \mu K\left(T_{j} e_{2}-e_{2}\right)\right)
\end{align*}
$$

By taking limit superior as $k \rightarrow \infty$ in the both-sides of (2.5), by using (2.3), we get

$$
\lim _{k \rightarrow \infty} \sum_{j=1}^{\infty} a_{k j}^{n} \rho\left(\mu\left(T_{j}(g ; \cdot)-g(\cdot)\right)\right)=0 \quad \text { uniformly in } n
$$

which proves our claim (2.4). Now let $f \in L^{\rho}(I)$ satisfying $f-g \in X_{\mathbb{T}}$ for every $g \in C^{\infty}(I)$. Since $|I|<\infty$ and $\rho$ is strongly finite and absolutely continuous, we can see that $\rho$ is also absolutely finite on $X(I)$ (see [4]). Using these properties of the modular $\rho$, it is known from $[6,14]$ that the space $C^{\infty}(I)$ is modularly dense in $L^{\rho}(I)$, i.e., there exists a sequence $\left\{g_{k}\right\} \subset C^{\infty}(I)$ such that

$$
\lim _{k} \rho\left(3 \lambda_{0}\left(g_{k}-f\right)\right)=0 \quad \text { for some } \lambda_{0}>0 .
$$

This means that, for every $\varepsilon>0$, there is a positive number $k_{0}=k_{0}(\varepsilon)$ so that

$$
\begin{equation*}
\rho\left(3 \lambda_{0}\left(g_{k}-f\right)\right)<\varepsilon \quad \text { for every } k \geq k_{0} . \tag{2.6}
\end{equation*}
$$

On the other hand, by the linearity and positivity of the operators $T_{j}$, we may write that

$$
\lambda_{0}\left|T_{j} f-f\right| \leq \lambda_{0}\left|T_{j}\left(f-g_{k_{0}}\right)\right|+\lambda_{0}\left|T_{j} g_{k_{0}}-g_{k_{0}}\right|+\lambda_{0}\left|g_{k_{0}}-f\right| .
$$

Applying the modular $\rho$ in the both-sides of the above inequality, since $\rho$ is monotone, we have

$$
\begin{align*}
\rho\left(\lambda_{0}\left(T_{j} f-f\right)\right) \leq & \rho\left(3 \lambda_{0}\left(T_{j} f-g_{k_{0}}\right)\right)+\rho\left(3 \lambda_{0}\left(T_{j} g_{k_{0}}-g_{k_{0}}\right)\right) \\
& +\rho\left(3 \lambda_{0}\left(g_{k_{0}}-f\right)\right) . \tag{2.7}
\end{align*}
$$

Then, it follows from (2.6) and (2.7) that

$$
\rho\left(\lambda_{0}\left(T_{j} f-f\right)\right) \leq \rho\left(3 \lambda_{0}\left(T_{j} f-g_{k_{0}}\right)\right)+\rho\left(3 \lambda_{0}\left(T_{j} g_{k_{0}}-g_{k_{0}}\right)\right)+\varepsilon .
$$

Hence, using the facts that $g_{k_{0}} \in C^{\infty}(I)$ and $f-g_{k_{0}} \in X_{\mathbb{T}}$, we have

$$
\begin{align*}
& \sum_{j=1}^{\infty} a_{k j}^{n} \rho\left(\lambda_{0}\left(T_{j} f-f\right)\right) \\
& \leq \sum_{j=1}^{\infty} a_{k j}^{n} \rho\left(3 \lambda_{0}\left(T_{j} f-g_{k_{0}}\right)\right)+\sum_{j=1}^{\infty} a_{k j}^{n} \rho\left(3 \lambda_{0}\left(T_{j} g_{k_{0}}-g_{k_{0}}\right)\right)+\varepsilon \sum_{j=1}^{\infty} a_{k j}^{n} . \tag{2.8}
\end{align*}
$$

Go back
From (2.2), there exists a constant $B>0$ such that $\sup _{n, k} \sum_{j=1}^{\infty} a_{k j}^{n}<B$. So, taking limit superior as $k \rightarrow \infty$ in the both-sides of (2.8), from (2.1) and (2.2) we obtain that

$$
\begin{aligned}
& \underset{k}{\lim \sup } \sum_{j=1}^{\infty} a_{k j}^{n} \rho\left(\lambda_{0}\left(T_{j} f-f\right)\right) \\
& \leq \varepsilon \limsup _{k} \sum_{j=1}^{\infty} a_{k j}^{n}+P \rho\left(3 \lambda_{0}\left(f-g_{k_{0}}\right)\right)+\limsup _{k} \sum_{j=1}^{\infty} a_{k j}^{n} \rho\left(3 \lambda_{0}\left(T_{j} g_{k_{0}}-g_{k_{0}}\right)\right),
\end{aligned}
$$

which gives

$$
\begin{align*}
& \underset{k}{\limsup } \sum_{j=1}^{\infty} a_{k j}^{n} \rho\left(\lambda_{0}\left(T_{j} f-f\right)\right) \\
& \leq \varepsilon(B+P)+\underset{k}{\limsup } \sum_{j=1}^{\infty} a_{k j}^{n} \rho\left(3 \lambda_{0}\left(T_{j} g_{k_{0}}-g_{k_{0}}\right)\right) . \tag{2.9}
\end{align*}
$$

By (2.4), since

$$
\lim _{k} \sum_{j=1}^{\infty} a_{k j}^{n} \rho\left(3 \lambda_{0}\left(T_{j} g_{k_{0}}-g_{k_{0}}\right)\right)=0, \quad \text { uniformly in } n
$$

we get

$$
\begin{equation*}
\limsup _{k} \sum_{j=1}^{\infty} a_{k j}^{n} \rho\left(3 \lambda_{0}\left(T_{j} g_{k_{0}}-g_{k_{0}}\right)\right)=0, \quad \text { uniformly in } n . \tag{2.10}
\end{equation*}
$$

Combining (2.9) with (2.10), we conclude that

$$
\underset{k}{\limsup } \sum_{j=1}^{\infty} a_{k j}^{n} \rho\left(\lambda_{0}\left(T_{j}(f ; x)-f(x)\right)\right) \leq \varepsilon(B+P) .
$$

Since $\varepsilon>0$ was arbitrary, we find

$$
\underset{k}{\lim \sup } \sum_{j=1}^{\infty} a_{k j}^{n} \rho\left(\lambda_{0}\left(T_{j} f-f\right)\right)=0 \quad \text { uniformly in } n .
$$

Furthermore, since $\sum_{j=1}^{\infty} a_{k j}^{n} \rho\left(\lambda_{0}\left(T_{j}(f ; x)-f(x)\right)\right)$ is non-negative for all $k, n \in \mathbb{N}$, we can easily show that

$$
\lim _{k} \sum_{j=1}^{\infty} a_{k j}^{n} \rho\left(\lambda_{0}\left(T_{j} f-f\right)\right)=0, \quad \text { uniformly in } n
$$

which completes the proof.
If the modular $\rho$ satisfies the $\Delta_{2}$-condition, then one can get the following result from Theorem 2.1 at once.

Theorem 2.2. Let $\mathcal{A}=\left(A^{n}\right)_{n \geq 1}$ be a sequence of infinite non-negative real matrices such that

$$
\sup _{n, k} \sum_{j=1}^{\infty} a_{k j}^{n}<\infty,
$$

and $\mathbb{T}:=\left\{T_{n}\right\}, \rho$ be the same as in Theorem 2.1. If $\rho$ satisfies the $\Delta_{2}$-condition, then the following statements are equivalent:
(a) $\lim _{k} \sum_{j=1}^{\infty} a_{k j}^{n} \rho\left(\lambda\left(T_{j} e_{i}-e_{i}\right)\right)=0 \quad$ uniformly in $n$ for every $\lambda>0$ and $i=0,1,2$,
(b) $\lim _{k} \sum_{j=1}^{\infty} a_{k j}^{n} \rho\left(\lambda\left(T_{j} f-f\right)\right)=0$ uniformly in $n$ for every $\lambda>0$ provided that $f$ is any function belonging to $L^{\rho}(I)$ such that $f-g \in X_{\mathbb{T}}$ for every $g \in C^{\infty}(I)$.

If $A^{n}=I$, identity matrix, then the condition (2.1) reduces to

$$
\begin{equation*}
\limsup _{j} \rho\left(\lambda\left(T_{j} h\right)\right) \leq P \rho(\lambda h) \tag{2.11}
\end{equation*}
$$

for every $h \in X_{\mathbb{T}}, \lambda>0$ and for an absolute positive constant $P$. In this case, the next results which were obtained by Bardaro and Mantellini [5] immediately follows from our Theorems 2.1 and 2.2.

Corollary 2.3. Let $\rho$ be a monotone, strongly finite, absolutely continuous and $N$-quasi semiconvex modular on $X(I)$. Let $\mathbb{T}:=\left\{T_{j}\right\}$ be a sequence of positive linear operators from $D$ into $X(I)$ satisfying (2.11). If $\left\{T_{j} e_{i}\right\}$ is strongly convergent to $e_{i}$ for each $i=0,1,2$, then $\left\{T_{j} f\right\}$ is modularly convergent to $f$ provided that $f$ is any function belonging to $L^{\rho}(I)$ such that $f-g \in X_{\mathbb{T}}$ for every $g \in C^{\infty}(I)$.

Corollary 2.4. $\mathbb{T}:=\left\{T_{j}\right\}$ and $\rho$ be the same as in Corollary 2.3. If $\rho$ satisfies the $\Delta_{2}$-condition, then the following statements are equivalent:
(a) $\left\{T_{j} e_{i}\right\}$ is strongly convergent to $e_{i}$ for each $i=0,1,2$,
(b) $\left\{T_{j} f\right\}$ is strongly convergent to $f$ provided that $f$ is any function belonging to $L^{\rho}(I)$ such that $f-g \in X_{\mathbb{T}}$ for every $g \in C^{\infty}(I)$.

## 3. Application

Take $I=[0,1]$ and let $\varphi:[0, \infty) \rightarrow[0, \infty)$ be a continuous function for which the following conditions hold:

- $\varphi$ is convex,
- $\varphi(0)=0, \varphi(u)>0$ for $u>0$ and $\lim _{u \rightarrow+\infty} \varphi(u)=\infty$.

Hence, consider the functional $\rho^{\varphi}$ on $X(I)$ defined by

$$
\rho^{\varphi}(f):=\int_{0}^{1} \varphi(|f(x)|) \mathrm{d} x \quad \text { for } \quad f \in X(I) .
$$

$44|4| \gg$
Go back

Full Screen

Close
In this case, $\rho^{\varphi}$ is a convex modular on $X(I)$, which satisfies all assumptions listed in Section 1 (see [5]). Consider the Orlicz space generated by $\varphi$ as follows

$$
L_{\varphi}^{\rho}(I):=\left\{f \in X(I): \rho^{\varphi}(\lambda f)<+\infty \quad \text { for some } \lambda>0\right\}
$$

Then, consider the following classical Bernstein-Kantorovich operator $\mathbb{U}:=\left\{U_{n}\right\}$ on the space $L_{\varphi}^{\rho}(I)$ (see [5]) which is defined by

$$
U_{j}(f ; x):=\sum_{k=0}^{j}\binom{j}{k} x^{k}(1-x)^{j-k}(j+1) \int_{k /(j+1)}^{(k+1) /(j+1)} f(t) \mathrm{d} t \quad \text { for } x \in I
$$

Observe that the operators $U_{j}$ map the Orlicz space $L_{\varphi}^{\rho}(I)$ into itself. Moreover, the property (2.11) is satisfied with the choice of $X_{\mathbf{U}}:=L_{\varphi}^{\rho}(I)$. Then, by Corollary 2.3, we know that, for every function $f \in L_{\varphi}^{\rho}(I)$ such that $f-g \in X_{\mathbf{U}}$ for every $g \in C^{\infty}(I),\left\{U_{j} f\right\}$ is modularly convergent to $f$.

Assume that $\mathcal{A}:=\left(A^{n}\right)_{n \geq 1}=\left(a_{k j}^{n}\right)_{k, j \in \mathbb{N}}$ is a sequence of infinite matrices defined by $a_{k j}^{n}=\frac{1}{k}$ if $n \leq j \leq k+n,(n=1,2, \ldots)$, and $a_{k j}^{n}=0$ otherwise, then $\mathcal{A}$-summability reduces to almost convergence. Define $s=\left(s_{n}\right)$ of the form
where $n_{1}$ is a multiple of $2, n_{2}$ is a multiple of $6, n_{3}$ is a multiple of $1,2, \ldots$ and $n_{k}$ is a multiple of $k(k+1)$. So $s$ is almost convergent to zero (see [15]). However, the sequence $\left\{s_{n}\right\}$ is not convergent to zero. Then, using the operators $U_{j}$, we define the sequence of positive linear operators $\mathbb{V}:=\left\{V_{n}\right\}$ on $L_{\varphi}^{\rho}(I)$ as follows:

$$
\begin{equation*}
V_{j}(f ; x)=\left(1+s_{j}\right) U_{j}(f ; x) \quad \text { for } f \in L_{\varphi}^{\rho}(I), x \in[0,1] \text { and } j \in \mathbb{N} \tag{3.2}
\end{equation*}
$$

where $s=\left\{s_{j}\right\}$ is the same as in (3.1). By [5, Lemma 5.1], for every $h \in X_{\mathbb{V}}:=L_{\varphi}^{\rho}(I)$, all $\lambda>0$ and for an absolute positive constant $P$, we get

$$
\begin{aligned}
\rho^{\varphi}\left(\lambda V_{j} h\right) & =\rho^{\varphi}\left(\lambda\left(1+s_{j}\right) U_{j} h\right) \leq \rho^{\varphi}\left(2 \lambda U_{j} h\right)+\rho^{\varphi}\left(2 \lambda s_{j} U_{j} h\right) \\
& =\rho^{\varphi}\left(2 \lambda U_{j} h\right)+s_{j} \rho^{\varphi}\left(2 \lambda U_{j} h\right)=\left(1+s_{j}\right) \rho^{\varphi}\left(2 \lambda U_{j} h\right) \leq\left(1+s_{j}\right) P \rho^{\varphi}(2 \lambda h) .
\end{aligned}
$$

Then, we get

$$
\limsup _{k}\left(\sup _{n} \frac{1}{k} \sum_{j=n}^{n+k} \rho^{\varphi}\left(\lambda V_{j} h\right)\right) \leq P \rho^{\varphi}(2 \lambda h) .
$$

So, the condition (2.1) works for our operators $V_{n}$ given by (3.2) with the choice of $X_{\mathbb{V}}=X_{\mathbb{U}}=$ $L_{\varphi}^{\rho}(I)$.

Now, we show that condition (2.3) in the Theorem 2.1 holds.
First observe that

$$
\begin{aligned}
& V_{j}\left(e_{0} ; x\right)=1+s_{j}, \\
& V_{j}\left(e_{1} ; x\right)=\left(1+s_{j}\right)\left(\frac{j x}{j+1}+\frac{1}{2(j+1)}\right), \\
& V_{j}\left(e_{2} ; x\right)=\left(1+s_{j}\right)\left(\frac{j(j-1) x^{2}}{(j+1)^{2}}+\frac{2 j x}{(j+1)^{2}}+\frac{1}{3(j+1)^{2}}\right) .
\end{aligned}
$$

$$
\rho^{\varphi}\left(\lambda\left(V_{j} e_{0}-e_{0}\right)\right)=\rho^{\varphi}\left(\lambda s_{j}\right)=\int_{0}^{1} \varphi\left(\lambda s_{j}\right) \mathrm{d} x=\varphi\left(\lambda s_{j}\right)=s_{j} \varphi(\lambda)
$$

because of the definition of $\left(s_{j}\right)$. Since $\left(s_{j}\right)$ is almost convergent to zero, we get

$$
\limsup _{k}\left(\sup _{n} \frac{1}{k} \sum_{j=n}^{n+k} \rho^{\varphi}\left(\lambda\left(V_{j} e_{0}-e_{0}\right)\right)\right)=0 \text { for every } \lambda>0
$$

which guarantees that (2.3) holds true for $i=0$. Also, since

$$
\begin{aligned}
\lambda\left|V_{j}\left(e_{1} ; x\right)-e_{1}(x)\right| & =\lambda\left|x\left(\frac{j}{j+1}+\frac{j s_{j}}{j+1}-1\right)+\frac{1}{2(j+1)}+\frac{s_{j}}{2(j+1)}\right| \\
& \leq \lambda|x|\left(\left|\frac{j}{j+1}-1\right|+\frac{j s_{j}}{j+1}\right)+\frac{1}{2(j+1)}+\frac{s_{j}}{2(j+1)} \\
& \leq \lambda\left\{\frac{1}{(j+1)}+\frac{2 j s_{j}}{2(j+1)}+\frac{s_{j}}{2(j+1)}+\frac{1}{2(j+1)}\right\} \\
& \leq \lambda\left\{\frac{3}{2(j+1)}+s_{j}\left(\frac{2 j+1}{2(j+1)}\right)\right\},
\end{aligned}
$$

we may write that

$$
\begin{aligned}
\rho^{\varphi}\left(\lambda\left(V_{j} e_{1}-e_{1}\right)\right) & \leq \rho^{\varphi}\left(\lambda\left\{s_{j}\left(\frac{2 j+1}{2(j+1)}\right)+\frac{3}{2(j+1)}\right\}\right) \\
& \leq s_{j} \rho^{\varphi}\left(\lambda\left(\frac{2 j+1}{j+1}\right)\right)+\rho^{\varphi}\left(\frac{3 \lambda}{j+1}\right)
\end{aligned}
$$

by the definitions of $\left(s_{j}\right)$ and $\rho^{\varphi}$. Since $\left(\frac{2 j+1}{j+1}\right)$ is convergent, it is bounded. So there exists a constant $M>0$ such that $\left(\frac{2 j+1}{j+1}\right) \leq M$ for every $j \in \mathbb{N}$. Then using the monotonicity of $\rho^{\varphi}$, we
have

$$
\rho^{\varphi}\left(\lambda\left(\frac{2 j+1}{j+1}\right)\right) \leq \rho^{\varphi}(\lambda M)
$$

for any $\lambda>0$, which implies

$$
\rho^{\varphi}\left(\lambda\left(V_{j} e_{1}-e_{1}\right)\right) \leq s_{j} \rho^{\varphi}(\lambda M)+\rho^{\varphi}\left(\frac{3 \lambda}{j+1}\right)=s_{j} \varphi(\lambda M)+\varphi\left(\frac{3 \lambda}{j+1}\right) .
$$

Since $\varphi$ is continuous, we have $\lim _{j} \varphi\left(\frac{3 \lambda}{j+1}\right)=\varphi\left(\lim _{j} \frac{3 \lambda}{j+1}\right)=\varphi(0)=0$. So, we get $\varphi\left(\frac{3 \lambda}{j+1}\right)$ is almost convergent to zero. Using $s$ and $\varphi\left(\frac{3 \lambda}{j+1}\right)$ are almost convergent to zero, we obtain

Close

$$
\begin{aligned}
& \limsup _{k}\left(\sup _{n} \frac{1}{k} \sum_{j=n}^{n+k} \rho^{\varphi}\left(\lambda\left(V_{j} e_{1}-e_{1}\right)\right)\right) \leq \underset{k}{\lim \sup _{p}}\left(\sup _{n} \frac{1}{k} \sum_{j=n}^{n+k}\left[s_{j} \varphi(\lambda M)+\varphi\left(\frac{3 \lambda}{j+1}\right)\right]\right) \\
& =\varphi(\lambda M) \limsup _{k}\left(\sup _{n} \frac{1}{k} \sum_{j=n}^{n+k} s_{j}\right)+\underset{k}{\lim \sup _{p}}\left(\sup _{n} \frac{1}{k} \sum_{j=n}^{n+k} \varphi\left(\frac{3 \lambda}{j+1}\right)\right)=0 .
\end{aligned}
$$

Finally, since

$$
\begin{aligned}
\lambda\left|V_{j}\left(e_{2} ; x\right)-e_{2}(x)\right|= & \lambda \left\lvert\, x^{2} \frac{j(j-1)}{(j+1)^{2}}+\frac{2 j x}{(j+1)^{2}}+\frac{1}{3(j+1)^{2}}\right. \\
& \left.+s_{j} \frac{j(j-1) x^{2}}{(j+1)^{2}}+s_{j} \frac{2 j x}{(j+1)^{2}}+s_{j} \frac{1}{3(j+1)^{2}}-x^{2} \right\rvert\, \\
\leq & \lambda x^{2}\left|\frac{j(j-1)}{(j+1)^{2}}-1\right|+x^{2} s_{j} \frac{j(j-1)}{(j+1)^{2}} \\
& +|x|\left(\frac{2 j}{(j+1)^{2}}+s_{j} \frac{2 j}{(j+1)^{2}}\right)+\frac{1}{3(j+1)^{2}}+s_{j} \frac{1}{3(j+1)^{2}} \\
\leq & \lambda\left\{\frac{3 j+1}{(j+1)^{2}}+s_{j} \frac{j(j-1)}{(j+1)^{2}}+\frac{2 j}{(j+1)^{2}}+s_{j} \frac{2 j}{(j+1)^{2}}\right. \\
& \left.+\frac{1}{3(j+1)^{2}}+s_{j} \frac{1}{3(j+1)^{2}}\right\} \\
\leq & \lambda\left\{\frac{15 j+4}{3(j+1)^{2}}+s_{j}\left(\frac{3 j^{2}+3 j+1}{3(j+1)^{2}}\right)\right\} .
\end{aligned}
$$

Since $\left(\frac{3 j^{2}+3 j+1}{3(j+1)^{2}}\right)$ is convergent, it is bounded. So there exists a constant $K>0$ such that $\left|\frac{3 j^{2}+3 j+1}{3(j+1)^{2}}\right| \leq K$ for every $j \in \mathbb{N}$. Then using the monotonicity of $\rho^{\varphi}$ and the definition of $\left(s_{j}\right)$, we
have

$$
\begin{aligned}
\rho^{\varphi}\left(\lambda\left(V_{j} e_{2}-e_{2}\right)\right) & \leq \rho^{\varphi}\left(2 \lambda\left(\frac{15 j+4}{3(j+1)^{2}}\right)\right)+\rho^{\varphi}\left(2 \lambda s_{j}\left(\frac{3 j^{2}+3 j+1}{3(j+1)^{2}}\right)\right) \\
& \leq \rho^{\varphi}\left(\lambda\left(\frac{30 j+8}{3(j+1)^{2}}\right)\right)+\rho^{\varphi}\left(2 \lambda s_{j} K\right)
\end{aligned}
$$

where which yields

$$
\begin{equation*}
\rho^{\varphi}\left(\lambda\left(V_{j} e_{2}-e_{2}\right)\right) \leq \varphi\left(\lambda\left(\frac{30 j+8}{3(j+1)^{2}}\right)\right)+s_{j} \varphi(2 \lambda K) \tag{3.3}
\end{equation*}
$$

Since $\varphi$ is continuous, we have $\lim _{j} \varphi\left(\lambda \frac{30 j+8}{3(j+1)^{2}}\right)=\varphi\left(\lambda \lim _{j} \frac{30 j+8}{3(j+1)^{2}}\right)=\varphi(0)=0$. So, we get $\varphi\left(\lambda \frac{30 j+8}{3(j+1)^{2}}\right)$ is almost convergent to zero. Using $s$ and $\varphi\left(\lambda \frac{30 j+8}{3(j+1)^{2}}\right)$ are almost convergent to zero, it follows from (3.3) that

$$
\limsup _{k}\left(\sup _{n} \frac{1}{k} \sum_{j=n}^{n+k} \rho^{\varphi}\left(\lambda\left(V_{j} e_{2}-e_{2}\right)\right)\right)=0 \quad \text { uniformly in } n \text { for every } \lambda>0 .
$$

Our claim (2.3) holds true for each $i=0,1,2$ and for any $\lambda>0$. So, we can say that our sequence $\mathbb{V}:=\left\{V_{j}\right\}$ defined by (3.2) satisfy all assumptions of Theorem 2.1. Therefore, we conclude that

$$
\limsup _{k}\left(\sup _{n} \frac{1}{k} \sum_{j=n}^{n+k} \rho^{\varphi}\left(\lambda_{0}\left(V_{j} f-f\right)\right)\right)=0 \text { uniformly in } n \text { for some } \lambda_{0}>0
$$

holds for every $f \in L_{\varphi}^{\rho}(I)$ such that $f-g \in X_{\mathbb{V}}=L_{\varphi}^{\rho}(I)$ for every $g \in C^{\infty}(I)$.

Go back
However, since $\left(s_{j}\right)$ is not convergent to zero, it is clear that $\left\{V_{j} f\right\}$ is not modularly convergent to $f$. So, Corollary 2.3 does not work for the sequence $\mathbb{V}:=\left\{V_{j}\right\}$.
