# On McDiarmid's concentration inequality 

Emmanuel Rio*

#### Abstract

In this paper we improve the rate function in the McDiarmid concentration inequality for separately Lipschitz functions of independent random variables. In particular the rate function tends to infinity at the boundary. We also prove that in some cases the usual normalization factor is not adequate and may be improved.

Keywords: McDiarmid inequality ; Concentration inequality ; Hoeffding inequality ; Vajda’s tight lower bound .

## 1 Introduction

Throughout the paper $\left(E_{1}, d_{1}\right), \ldots,\left(E_{n}, d_{n}\right)$ is a finite sequence of separable metric spaces with positive finite diameters $\Delta_{1}, \ldots, \Delta_{n}$. Let $E^{n}=E_{1} \times \cdots \times E_{n}$. A function $f$ from $E^{n}$ into $\mathbb{R}$ is said to be separately 1-Lipschitz if

$$
\left|f\left(x_{1}, \ldots, x_{n}\right)-f\left(y_{1}, \ldots, y_{n}\right)\right| \leq d_{1}\left(x_{1}, y_{1}\right)+\cdots+d_{n}\left(x_{n}, y_{n}\right) .
$$

Let $(\Omega, \mathcal{T}, \mathbb{P})$ be a probability space and $X=\left(X_{1}, \ldots, X_{n}\right)$ be a random vector with independent components, with values in $E^{n}$. Let $f$ be any separately 1-Lipschitz function from $E^{n}$ into $\mathbb{R}$. Set

$$
\begin{equation*}
Z=f(X)=f\left(X_{1}, \ldots, X_{n}\right) \tag{1.1}
\end{equation*}
$$

Let the McDiarmid diameter $\sigma_{n}$ be defined by

$$
\begin{equation*}
\sigma_{n}^{2}=\Delta_{1}^{2}+\Delta_{2}^{2}+\cdots+\Delta_{n}^{2} . \tag{1.2}
\end{equation*}
$$

McDiarmid [9], [10] proved that, for any positive $x$,

$$
\begin{equation*}
\mathbb{P}\left(Z-\mathbb{E}(Z) \geq \sigma_{n} x\right) \leq \exp \left(-2 x^{2}\right) \tag{1.3}
\end{equation*}
$$

This inequality is an extension of Theorem 2 in Hoeffding [6]. We refer to [4], Chapter 2, for more about concentration inequalities. Later Bentkus [3] (paper submitted on August 17, 2001) and Pinelis [12] replaced the upper bound in (1.3) by a Gaussian tail function. They proved that

$$
\begin{equation*}
\mathbb{P}\left(Z-\mathbb{E}(Z) \geq \sigma_{n} x\right) \leq c \mathbb{P}(Y \geq 2 x), \text { with } Y \stackrel{D}{=} N(0,1) \tag{1.4}
\end{equation*}
$$

[^0]The best known constant in (1.4) is $c=5.70$, due to [12]. In the real-valued case, the bounds may be much better in the moderate deviations area when the standard deviations of the random variables are significantly smaller than the diameters $\Delta_{i}$. Furthermore the random variables do not need to be bounded from below. We refer to [1], [2], [7], [11] and [12] for more about this subject, which is essentially outside the scope of this paper. Here we do not impose conditions on the variances of the random variables. More precisely, our aim is to get upper bounds for the quantity $P_{M c D}(z, \Delta)$ introduced before Inequality (1.9) below.

We now comment on the results (1.3) and (1.4). Since $f$ is separately 1-Lipschitz and the spaces $E_{i}$ have a finite diameter $\Delta_{i}$, the function $f$ is uniformly bounded over $E^{n}$. Furthermore if $M=\sup _{E^{n}} f$ and $m=\inf _{E^{n}} f$, then

$$
\begin{equation*}
m \leq Z \leq M \text { and } M-m \leq \Delta_{1}+\Delta_{2}+\cdots+\Delta_{n}:=D_{n} \tag{1.5}
\end{equation*}
$$

From (1.5) it follows that

$$
\begin{equation*}
\mathbb{P}\left(Z-\mathbb{E}(Z) \geq D_{n}\right)=\mathbb{P}(Z=M \text { and } \mathbb{E}(Z)=m)=0 \tag{1.6}
\end{equation*}
$$

Now (1.6) cannot be deduced from either (1.3) or (1.4). Hence it seems clear that the rate function $2 x^{2}$ in the McDiarmid inequality (1.3) is suboptimal for large values of $x$. One of the goals of this paper is to improve the rate function appearing in (1.3). In Section 2, we give a more efficient large deviations rate function in the case $\Delta_{1}=\Delta_{2}=$ $\cdots=\Delta_{n}=1$. In particular we prove that, for any $x$ in $[0,1]$,

$$
\begin{equation*}
\mathbb{P}(Z-\mathbb{E}(Z) \geq n(1-x)) \leq x^{n\left(1-x^{2}\right)} \tag{1.7}
\end{equation*}
$$

This inequality implies (1.3) and yields (1.6). Next, in Section 3, we extend the results of Section 2 to the case of distinct diameters, for small values or large values of the deviation. In Theorem 3.1 we give the following extension of (1.7): for any $x$ in $[0,1]$,

$$
\begin{equation*}
\mathbb{P}\left(Z-\mathbb{E}(Z) \geq D_{n}(1-x)\right) \leq x^{\left(1-x^{2}\right) D_{n}^{2} / \sigma_{n}^{2}} \tag{1.8}
\end{equation*}
$$

We now recall the known lower bounds for large values of the deviations. Take $E_{i}=$ $\left[0, \Delta_{i}\right]$. Let $\Delta=\left(\Delta_{1}, \Delta_{2}, \ldots, \Delta_{n}\right)$ and let $P_{M c D}(z, \Delta)$ be defined as the maximal value of $\mathbb{P}(Z-\mathbb{E}(Z) \geq z)$ over all the separately 1-Lipschitz functions and all the random vectors $X$ with values in $E$ and with independent components. By Proposition 5.7 in Ohwadi et al. [11],

$$
\begin{equation*}
P_{M c D}\left(D_{n}-n x, \Delta\right) \geq x^{n} /\left(\Delta_{1} \Delta_{2} \ldots \Delta_{n}\right) \text { for any } x \leq \min \left(\Delta_{1}, \Delta_{2}, \ldots, \Delta_{n}\right) \tag{1.9}
\end{equation*}
$$

As shown by the converse inequality (1.9), (1.8) is suitable for large values of the deviation when $\sigma_{n}^{2} \sim D_{n}^{2} / n$. Nevertheless (1.8) has to be improved when $\sigma_{n} \gg n^{-1 / 2} D_{n}$. In Theorem 3.2 of Section 3, we prove the converse inequality of (1.9) with $D_{n}-(56 / 67) n x$ instead of $D_{n}-n x$. Finally we give a more general inequality in Section 5. This inequality, based on partitions of the set of diameters, provides better numerical estimates than the results of Section 3 for intermediate values of the deviation. Section 4 is devoted to the proofs of the results of Sections 2 and 3.

## 2 The case of equality of the diameters

In this section we assume that $\Delta_{1}=\Delta_{2}=\cdots=\Delta_{n}=1$. Then (1.3) yields

$$
\mathbb{P}(Z-\mathbb{E}(Z) \geq n x) \leq \exp \left(-n \varphi_{0}(x)\right) \text { with } \varphi_{0}(x)=2 x^{2}
$$

For $x=1, \varphi_{0}(1)=2<\infty$. Hence Inequality (1.3) does not imply (1.6). In Theorem 2.1 below, we give a better large deviations rate function for large values of $x$.

## On McDiarmid's concentration inequality

Theorem 2.1. Let $Z$ be defined by (1.1). For any positive $t$,

$$
\begin{equation*}
n^{-1} \log \mathbb{E}(\exp (t Z-t \mathbb{E}(Z))) \leq(t-\log t-1)+t\left(e^{t}-1\right)^{-1}+\log \left(1-e^{-t}\right):=\ell(t) \tag{a}
\end{equation*}
$$

Let the rate functions $\psi_{1}$ and $\psi_{2}$ be defined by

$$
\begin{equation*}
\psi_{1}(x)=2 x^{2}+4 x^{4} / 9, \psi_{2}(x)=\left(x^{2}-2 x\right) \log (1-x) \text { for } x \in[0,1[ \tag{2.1}
\end{equation*}
$$

and $\psi_{2}(x)=+\infty$ for $x \geq 1$. Let $\ell^{*}$ denote the Young transform of $\ell$, which is defined by $\ell^{*}(x)=\sup _{t>0}(x t-\ell(t))$. For any positive $x$,

$$
\begin{equation*}
\ell^{*}(x) \geq \max \left(\psi_{1}(x), \psi_{2}(x)\right) \tag{b}
\end{equation*}
$$

Consequently, by the usual Chernoff calculation, for any $x$ in $[0,1]$,

$$
\begin{equation*}
\mathbb{P}(Z-\mathbb{E}(Z) \geq n x) \leq \exp \left(-n \max \left(\psi_{1}(x), \psi_{2}(x)\right)\right) \leq(1-x)^{n\left(2 x-x^{2}\right)} \tag{c}
\end{equation*}
$$

Remark 2.1. In Section 4, it is shown that $\psi_{2}(x) \geq 2 x^{2}+x^{4} / 6$. Consequently the second part of Theorem 2.1(c) also improves (1.3). Now, by (1.9) and Theorem 2.1(b),

$$
\begin{equation*}
-\log (1-x)+(1-x)^{2} \log (1-x) \leq \ell^{*}(x) \leq-\log (1-x) \text { for any } x \in[0,1[ \tag{2.2}
\end{equation*}
$$

Hence $\lim _{x \uparrow 1}\left(\ell^{*}(x)+\log (1-x)\right)=0$, which gives the asymptotics of $\ell^{*}$ as $x \uparrow 1$.
Remark 2.2. It comes from Lemma 4.3(a) in Section 4 that $\ell^{*}(x)=L_{V}(2 x)$, where $L_{V}$ is the information function defined in Equation (3) in Vajda [16]. Vajda proved that $L_{V}(2 x) \geq-\log (1-x)+\log (1+x)-2 x /(1+x)$. Theorem 2.1 in Gilardoni [5] gives the better lower bound $L_{V}(2 x) \geq-\log (1-x)-(1-x) \log (1+x):=L_{2}(2 x)$. Using the concavity of the logarithm function, it can easily be proven that $\psi_{2}(x)>L_{2}(2 x)$. Hence the lower bound $\ell^{*} \geq \psi_{2}$ improves Gilardoni's lower bound.
Remark 2.3. The expansion of $\ell$ at point 0 of order 5 is $\ell(t)=t^{2} / 8-t^{4} / 576+O\left(t^{6}\right)$. It follows that $\ell^{*}(x)=2 x^{2}+(4 / 9) x^{4}+O\left(x^{6}\right)$ as $x$ tends to 0 . Hence $\psi_{1}$ is the exact expansion of $\ell^{*}$ of order 5. The lower bound $\ell^{*} \geq \psi_{1}$ is based on Inequality (2) in Krafft [8]. Using Corollary 1.4 in Topsøe [15], one can obtain the slightly better lower bound $\ell^{*} \geq \psi_{3}$, where $\psi_{3}$ is defined by $\psi_{3}(x)=\psi_{1}(x)+(32 / 135) x^{6}+(7072 / 42525) x^{8}$.

## 3 The general case: moderate and large deviations

Here we assume that the diameters $\Delta_{i}$ do not satisfy $\Delta_{1}=\Delta_{2}=\cdots=\Delta_{n}$. Let us introduce the quantities below, which will be used to state our bounds:

$$
\begin{equation*}
D_{n}=\Delta_{1}+\Delta_{2}+\cdots+\Delta_{n}, A_{n}=D_{n} / n \text { and } G_{n}=\left(\Delta_{1} \Delta_{2} \ldots \Delta_{n}\right)^{1 / n} \tag{3.1}
\end{equation*}
$$

Then $G_{n}<A_{n}$. Our first result is an extension of Theorem 2.1, which preserves the variance factor $\sigma_{n}^{2}$. This result is suitable for moderate deviations. Here $\ell$ denotes the function already defined in Theorem 2.1(a) and $\ell^{*}$ is the Young transform of $\ell$.

Theorem 3.1. Let $Z$ be defined by (1.1). For any positive $t$,

$$
\begin{equation*}
\log \mathbb{E}(\exp (t Z-t \mathbb{E}(Z))) \leq\left(D_{n} / \sigma_{n}\right)^{2} \ell\left(\sigma_{n}^{2} t / D_{n}\right) \tag{a}
\end{equation*}
$$

Consequently, for any $x$ in $[0,1]$,

$$
\begin{equation*}
\mathbb{P}\left(Z-\mathbb{E}(Z) \geq D_{n} x\right) \leq \exp \left(-\left(D_{n} / \sigma_{n}\right)^{2} \ell^{*}(x)\right) \tag{b}
\end{equation*}
$$

Contrary to the McDiarmid inequality, the upper bound in Theorem 3.1(b) converges to 0 as $x$ tends to 1 . Now, by the Cauchy-Schwarz inequality, $\left(D_{n} / \sigma_{n}\right)^{2} \leq n$ in the general case. Moreover, in some cases $\left(D_{n} / \sigma_{n}\right)^{2}=o(n)$ as $n$ tends to $\infty$. In that case Theorem 3.2 below provides better results for large values of $x$. In order to state this result we need to introduce a second rate function. This is done in Proposition 3.1. below.
Proposition 3.1. Let $\eta(t)=\ell(t)-(t-\log t-1)$ and let $t_{0} \simeq 1.5936$ be the solution of the equation $1-e^{-t}=t / 2$. Then $\eta$ is concave and increasing on $\left.] 0, t_{0}\right]$ and decreasing on $\left[t_{0}, \infty\right.$. Furthermore $\eta^{\prime}\left(t_{0}\right)=0$ and consequently $\ell^{\prime}\left(t_{0}\right)=1-t_{0}^{-1}$. Define the function $\eta_{c}$ be defined by $\eta_{c}(t)=\eta(t)$ for $t$ in $\left.] 0, t_{0}\right]$ and $\eta_{c}(t)=\eta\left(t_{0}\right)$ for $t \geq t_{0}$. Let $\ell_{c}$ be defined by $\ell_{c}(t)=(t-\log t-1)+\eta_{c}(t)$. Then $\ell_{c}$ is a convex, continuously differentiable and increasing function on $\mathbb{R}^{+}$, and

$$
\begin{equation*}
\ell_{c}^{*}(x)=\ell^{*}(x) \text { for } x \leq \ell^{\prime}\left(t_{0}\right) \text { and } \ell_{c}^{*}(x)=-\eta\left(t_{0}\right)-\log (1-x) \text { for } x \in\left[\ell^{\prime}\left(t_{0}\right), 1[.\right. \tag{a}
\end{equation*}
$$

The numerical value of $\eta\left(t_{0}\right)$ is $\eta\left(t_{0}\right) \simeq 0.17924$. Furthermore

$$
\begin{equation*}
\ell_{c}(t) \leq t^{2} / 8 \text { for any } t>0 \text { and } \ell_{c}^{*}(x) \geq 2 x^{2} \text { for any } x>0 \tag{b}
\end{equation*}
$$

We now state our second result.
Theorem 3.2. Let $Z$ be defined by (1.1). For any positive $t$,

$$
\begin{equation*}
n^{-1} \log \mathbb{E}(\exp (t Z-t \mathbb{E}(Z))) \leq \log \left(A_{n} / G_{n}\right)+\ell_{c}\left(A_{n} t\right) \tag{a}
\end{equation*}
$$

Let $t_{0}$ be defined as in Proposition 3.1 and let $x_{0}=\ell^{\prime}\left(t_{0}\right)=1-t_{0}^{-1}$. The numerical value of $x_{0}$ is $x_{0} \simeq 0.3725$. For $x$ in [ $\left.0, x_{0}\right]$,

$$
\begin{equation*}
\mathbb{P}\left(Z-\mathbb{E}(Z) \geq D_{n} x\right) \leq \exp \left(n \log \left(A_{n} / G_{n}\right)-n \ell^{*}(x)\right) \tag{b}
\end{equation*}
$$

and, for $x$ in $\left[x_{0}, 1\right]$,

$$
\begin{equation*}
\mathbb{P}\left(Z-\mathbb{E}(Z) \geq D_{n} x\right) \leq \exp \left(n \log \left(A_{n} / G_{n}\right)+n \eta\left(t_{0}\right)\right)(1-x)^{n} \tag{c}
\end{equation*}
$$

Remark 3.1. Since the maximum value of $\eta_{c}$ is $\eta\left(t_{0}\right), \ell_{c}(t) \leq t-\log t-1+\eta\left(t_{0}\right)$ for any positive $t$. Hence, for any $x$ in $[0,1[$,

$$
\begin{equation*}
\ell_{c}^{*}(x) \geq-\eta\left(t_{0}\right)-\log (1-x) \geq \log (56 / 67)-\log (1-x) \tag{3.2}
\end{equation*}
$$

It follows that, for any positive $y$,

$$
\begin{equation*}
\mathbb{P}\left(Z-\mathbb{E}(Z) \geq D_{n}-(56 / 67) n y\right) \leq y^{n} /\left(\Delta_{1} \Delta_{2} \ldots \Delta_{n}\right) \tag{3.3}
\end{equation*}
$$

The factor $1 /\left(\Delta_{1} \Delta_{2} \ldots \Delta_{n}\right)$ appearing in (3.3) cannot be removed, as shown by (1.9). For sake of completeness, we give here the proof of (1.9). let $\Delta_{1} \geq \Delta_{2} \geq \cdots \geq \Delta_{n}$ be positive reals and $y$ be any positive real in $\left[0, \Delta_{n}\right]$. Let $b_{1}, \ldots, b_{k}, \ldots, b_{n}$ be independent random variables with Bernoulli laws $b\left(y / \Delta_{k}\right)$. Set $T_{n}=\Delta_{1} b_{1}+\Delta_{2} b_{2}+\cdots+\Delta_{n} b_{n}$. Then $\mathbb{P}\left(T_{n}-\mathbb{E}\left(T_{n}\right) \geq D_{n}-n y\right)=y^{n} /\left(\Delta_{1} \Delta_{2} \ldots \Delta_{n}\right)$.

Example 3.1. Take $n=100, \Delta_{1}=49$ and $\Delta_{k}=1$ for $k \geq 2$. Then $\sigma_{n}=50, D_{n}=148$ and $A_{n}=1.48$. Let $p=\mathbb{P}(Z-\mathbb{E}(Z) \geq 75)$. The McDiarmid inequality (1.3) applied with $x=3 / 2$ yields $p \leq e^{-9 / 2} \simeq 1.110^{-2}$ and (1.4) yields $p \leq 7.710^{-3}$. Theorem 3.1(b) together with the lower bound $\ell^{*} \geq \psi_{3}$ (see Remark 2.3) yields $p \leq 8.310^{-3}$. Theorem 3.2(c) applied with $x=75 / 148\left(x>x_{0}\right)$ yields $p \leq 2.710^{-8}$.

## 4 Proofs of the results of Sections 2 and 3

We start by proving an upper bound on the Laplace transform of $Z$ which implies Theorem 2.1(a) in the case $\Delta_{1}=\Delta_{2}=\ldots=\Delta_{n}$.

Lemma 4.1. Let $\ell$ be the function already defined in Theorem 2.1(a). Then, for any positive $t, \log \mathbb{E}(\exp (t Z-t \mathbb{E}(Z))) \leq \ell\left(\Delta_{1} t\right)+\ell\left(\Delta_{2} t\right)+\cdots+\ell\left(\Delta_{n} t\right):=L(t)$.

Proof of Lemma 4.1. Let us briefly recall the martingale decomposition of $Z$. Let $\mathcal{F}_{0}=$ $\{\emptyset, \Omega\}$ and $\mathcal{F}_{k}=\sigma\left(X_{1}, \ldots, X_{k}\right)$. Set $Z_{k}=\mathbb{E}\left(Z \mid \mathcal{F}_{k}\right)$. Then $Z=Z_{n}$ and $Z_{0}=\mathbb{E}(Z)$. Furthermore $\left(Z_{k}\right)_{k}$ is a martingale sequence adapted to the above filtration. Now, set $Y_{k}=Z_{k}-Z_{k-1}$. Define the $\mathcal{F}_{k-1}$-measurable random variable $W_{k-1}$ by

$$
\begin{equation*}
W_{k-1}=\mathbb{E}\left(\inf _{x \in E_{k}} f\left(X_{1}, \ldots X_{k-1}, x, X_{k+1}, \ldots, X_{n}\right) \mid \mathcal{F}_{k-1}\right)-Z_{k-1} \tag{4.1}
\end{equation*}
$$

By the Lipschitz condition on $f, W_{k-1} \leq Y_{k} \leq W_{k-1}+\Delta_{k}$ (see [10]). From this inequality and the convexity of the exponential function,

$$
\begin{equation*}
\Delta_{k} e^{t Y_{k}} \leq\left(Y_{k}-W_{k-1}\right) e^{t\left(W_{k-1}+\Delta_{k}\right)}+\left(\Delta_{k}+W_{k-1}-Y_{k}\right) e^{t W_{k-1}} \tag{4.2}
\end{equation*}
$$

Hence, using the martingale property,

$$
\begin{equation*}
\Delta_{k} \mathbb{E}\left(e^{t Y_{k}} \mid \mathcal{F}_{k-1}\right) \leq-W_{k-1} e^{t\left(W_{k-1}+\Delta_{k}\right)}+\left(\Delta_{k}+W_{k-1}\right) e^{t W_{k-1}} \tag{4.3}
\end{equation*}
$$

Set then

$$
\begin{equation*}
\gamma(r, t)=\log \left(1+r\left(e^{t}-1\right)\right)-t r \text { and } r_{k-1}=-\left(W_{k-1} / \Delta_{k}\right) \tag{4.4}
\end{equation*}
$$

Since $\left(Z_{k}\right)$ is a martingale sequence, $\mathbb{E}\left(Y_{k} \mid \mathcal{F}_{k-1}\right)=0$. Hence, from (4.2), $W_{k-1} \leq 0$ and $0 \leq W_{k-1}+\Delta_{k}$. Consequently $r_{k-1}$ belongs to [0,1]. Now, starting from (4.3) and using the definitions (4.4), we get that $\log \mathbb{E}\left(e^{t Y_{k}} \mid \mathcal{F}_{k-1}\right) \leq \gamma\left(r_{k-1}, \Delta_{k} t\right)$. Define now

$$
\begin{equation*}
\ell(t)=\sup _{r \in[0,1]} \gamma(r, t)=\sup _{r \in] 0,1[ }\left(\log \left(1+r\left(e^{t}-1\right)\right)-t r\right) \tag{4.5}
\end{equation*}
$$

From the above inequalities $\log \mathbb{E}\left(e^{t Y_{k}} \mid \mathcal{F}_{k-1}\right) \leq \ell\left(\Delta_{k} t\right)$ almost surely, which implies Lemma 4.1 for the function $\ell$ defined in (4.5). It remains to prove that $\ell$ is equal to the function already defined in Theorem 2.1(a). Now

$$
\frac{\partial \gamma}{\partial r}(r, t)=\frac{e^{t}-t-1-r t\left(e^{t}-1\right)}{1+r\left(e^{t}-1\right)}
$$

and consequently the function $\gamma(r, t)$ has an unique maximum with respect to $r$ in the interval $[0,1]$. This maximum is obtained for $r=r_{t}=\left(e^{t}-t-1\right) /\left(t\left(e^{t}-1\right)\right)$, whence

$$
\ell(t)=\log \left(\left(e^{t}-1\right) / t\right)-1+t /\left(e^{t}-1\right)=(t-\log t-1)+t\left(e^{t}-1\right)^{-1}+\log \left(1-e^{-t}\right) .
$$

We now prove Theorem 2.1(b). The first step is to compare the functions $\psi_{1}$ and $\psi_{2}$.
Lemma 4.2. There exists a unique real $x_{0}$ in [0.6670, 0.6675] such that $\psi_{1}(x) \geq \psi_{2}(x)$ for any $x \leq x_{0}$ and $\psi_{1}(x)<\psi_{2}(x)$ for $x>x_{0}$.

Proof of Lemma 4.2. For any real $x$ in $\left[0,1\left[, \psi_{2}(x)=2 x^{2}+\left(x^{4} / 6\right)+\sum_{k>4} a_{k} x^{k}\right.\right.$ with $a_{k}=(k-3) /\left(k^{2}-3 k+2\right)$. Define now $f$ by $f(x)=x^{-4}\left(\psi_{2}(x)-\psi_{1}(x)\right)$ for $x$ in $[0,1[$. Then $f(x)=(-5 / 18)+\sum_{k>4} a_{k} x^{k-4}$, which implies that $f$ is increasing on [0,1]. Lemma 4.2 follows then from the facts that $f(0.6670)<0$ and $f(0.6675)>0$.

## On McDiarmid's concentration inequality

The second step is to prove that $\ell^{*}(x) \geq \psi_{1}(x)$ for any $x$ in $[0,1]$.
Lemma 4.3. For any $r$ in $] 0,1\left[\right.$, let the function $h_{r}$ be defined by

$$
h_{r}(x)=(r+x) \log (1+x / r)+(1-r-x) \log (1-x /(1-r)) \text { for } x \text { in }[0,1-r[\text {, }
$$

$h_{r}\left((1-r)=-\log r\right.$ and $h_{r}(x)=+\infty$ for $x>1-r$. Then

$$
\begin{equation*}
\ell^{*}(x)=\inf _{r \in] 0,1[ } h_{r}(x) \text { for any } x>0 \tag{a}
\end{equation*}
$$

Consequently $\ell^{*}(x) \geq \psi_{1}(x)$ for any $x$ in $[0,1]$.
Proof of Lemma 4.3. From (4.5), for any positive $x$,

$$
\ell^{*}(x)=\sup _{t>0} \inf _{r \in[0,1-x]}(t x-\gamma(r, t)) .
$$

Now the function $(r, t) \rightarrow t x-\gamma(r, t)$ is convex in $r$ and concave in $t$. Hence, the minimax theorem (see Corollary 3.3 in [14], for example) applies and yields

$$
\begin{equation*}
\ell^{*}(x)=\inf _{r \in[0,1-x]} \sup _{t>0}(t x-\gamma(r, t)) \tag{4.6}
\end{equation*}
$$

Let then $\gamma_{r}^{*}(x)=\sup _{t>0}(t x-\gamma(r, t))$. As proved by Hoeffding [6],

$$
\begin{equation*}
\gamma_{r}^{*}(x)=(r+x) \log (1+x / r)+(1-r-x) \log (1-x /(1-r)) \text { for } x \text { in }[0,1-r[ \tag{4.7}
\end{equation*}
$$

and $\gamma_{r}^{*}(1-r)=-\log r$. Moreover $\gamma_{r}^{*}(x)=+\infty$ for $x>1-r$. Hence (4.6) and (4.7) yield Lemma 4.3(a). Now, by Inequality (2) in $\operatorname{Krafft}[8], \gamma_{r}^{*}(x) \geq \psi_{1}(x)$ for any $r$ in $] 0,1-x$ ], which completes the proof of Lemma 4.3.

To prove Theorem 2.1(b), it remains to prove that

$$
\begin{equation*}
\ell^{*}(x) \geq \psi_{2}(x) \text { for any } x \geq x_{0} \tag{4.8}
\end{equation*}
$$

This inequality is a direct consequence of Lemma 4.4 below together with the fact that $-\log (1-x) \geq 1$ for $x \geq 2 / 3$.

Lemma 4.4. $\ell^{*}(x) \geq-\log (1-x)-(1-x)^{2}$ for any $x \geq 2 / 3$.
Proof of Lemma 4.4. Let $\eta$ be the function which is defined in Proposition 3.1. Set $t_{x}=$ $1 /(1-x)$. By definition of $\ell^{*}, \ell^{*}(x) \geq x t_{x}-\ell\left(t_{x}\right)=\log t_{x}-\eta\left(t_{x}\right)$. Now, if $x \geq 2 / 3$, then $t_{x} \geq 3$. Consequently the proof of Lemma 4.4 will be complete if we prove that

$$
\begin{equation*}
t^{2} \eta(t) \leq 1 \text { for any } t \geq 3 \tag{4.9}
\end{equation*}
$$

By concavity of the logarithm,

$$
t^{2} \eta(t) \leq t^{2}\left(t\left(e^{t}-1\right)^{-1}-e^{-t}\right)=\left(t^{2}+\left(t^{3}-t^{2}\right) e^{t}\right) /\left(e^{2 t}-e^{t}\right)
$$

Hence the inequality $t^{2} \eta(t) \leq 1$ holds true if $\delta(t):=\left(e^{t}+t^{2}-t^{3}-1\right) e^{t}-t^{2} \geq 0$ for $t \geq 3$. Let $\beta(t):=e^{t}+t^{2}-t^{3}-1$. $\beta$ is strictly convex on $[3, \infty[$ and has a unique minimum at $t_{0} \simeq 3.1699$. Now $\beta\left(t_{0}\right) \simeq 1.00137>1$, whence $\delta(t)>e^{t}-t^{2}>0$ for $t \geq 3$. Hence (4.9) holds true, which implies Lemma 4.4.

Proof of Theorem 2.1(b). Theorem 2.1(b) follows from Lemmas 4.2 and 4.3 together with (4.8).

## On McDiarmid's concentration inequality

Proof of Theorem 3.1. The proof of Theorem 3.1 is based on the concavity property below.

Lemma 4.5. The function $\ell^{\prime}$ is concave on $\mathbb{R}^{+}$.
Proof of Lemma 4.5. Set $v=1 /\left(e^{t}-1\right)$. Then $\ell(t)=v t-\log v-\log t-1$. Since $v^{\prime}=$ $-v(1+v)$,

$$
\begin{equation*}
\ell^{\prime}=1+2 v-t v-t v^{2}-(1 / t), \ell^{\prime \prime}=-3\left(v+v^{2}\right)+t v(1+v)(1+2 v)+\left(1 / t^{2}\right) \tag{4.10}
\end{equation*}
$$

and

$$
\begin{equation*}
-\ell^{\prime \prime \prime}=\left(2 / t^{3}\right)-4 v(1+v)(1+2 v)+t v(1+v)(1+6 v(1+v)) \tag{4.11}
\end{equation*}
$$

Let $f(t):=-\ell^{\prime \prime \prime}(t) /\left(t v^{2}(1+v)^{2}\right)$. We prove that $f \geq 0$. Since $2 v(1+v)(\cosh t-1)=1$, the function $f$ can be decomposed as follows:

$$
f(t)=f_{1}(t)+f_{2}(t) \text { with } f_{1}(t)=8 t^{-4}(\cosh t-1)^{2} \text { and } f_{2}(t)=2 \cosh t+4-8(\sinh t / t)
$$

Now $f_{1}$ and $f_{2}$ are analytic. First $f_{2}(t)=-2-\left(t^{2} / 3\right)+\sum_{k \geq 2} a_{k} t^{2 k}$, for positive coefficients $a_{k}$. More precisely $a_{k}=2(2 k-3) /(2 k+1)$ !. Consequently $f_{2}(t) \geq-2-\left(t^{2} / 3\right)$. And second $2(\cosh t-1) \geq t^{2}\left(1+t^{2} / 12\right)$, whence

$$
f_{1}(t)+f_{2}(t) \geq 2\left(1+t^{2} / 12\right)^{2}-2-t^{2} / 3=t^{4} / 72>0
$$

Hence $f(t)>0$ for any positive $t$, which ensures that $\ell^{\prime}$ is concave.
We now complete the proof of Theorem 3.1. According to Lemma 4.1, we have to prove that

$$
\begin{equation*}
L(t):=\ell\left(\Delta_{1} t\right)+\ell\left(\Delta_{2} t\right)+\cdots+\ell\left(\Delta_{n} t\right) \leq\left(D_{n} / \sigma_{n}\right)^{2} \ell\left(\sigma_{n}^{2} t / D_{n}\right) \tag{4.12}
\end{equation*}
$$

Now

$$
L(t)=\int_{0}^{t} L^{\prime}(u) d u=\int_{0}^{t}\left(\Delta_{1} \ell^{\prime}\left(\Delta_{1} u\right) \cdots+\Delta_{n} \ell^{\prime}\left(\Delta_{n} u\right)\right) d u
$$

Next, by Lemma 4.5,

$$
\Delta_{1} \ell^{\prime}\left(\Delta_{1} u\right) \cdots+\Delta_{n} \ell^{\prime}\left(\Delta_{n} u\right) \leq D_{n} \ell^{\prime}\left(\sigma_{n}^{2} u / D_{n}\right)
$$

Hence

$$
L(t) \leq D_{n} \int_{0}^{t} \ell^{\prime}\left(\sigma_{n}^{2} u / D_{n}\right) d u=\left(D_{n} / \sigma_{n}\right)^{2} \ell\left(\sigma_{n}^{2} t / D_{n}\right)
$$

Hence (4.12) holds, which implies Theorem 3.1(a). Theorem 3.1(b) follows from the usual Chernoff calculation.

Proof of Proposition 3.1. With the notations of the proof of Lemma 4.5,

$$
\eta^{\prime}=v(2-(1+v) t) \text { and } \eta^{\prime \prime}=v(1+v)(t(1+2 v)-3)
$$

Therefrom $\eta^{\prime}(t)>0$ if and only if $2>t e^{t} /\left(e^{t}-1\right)$, which holds for $t>0$ if and only $t<t_{0}$. Moreover $\eta^{\prime}\left(t_{0}\right)=0$ and $\eta^{\prime}(t)<0$ for $t<t_{0}$. Hence $\eta$ is increasing on $\left[0, t_{0}\right]$ and decreasing on $\left[t_{0}, \infty\left[\right.\right.$. Now $\eta^{\prime \prime}(t)<0$ if and only if $t\left(e^{t}+1\right)<3\left(e^{t}-1\right)$. This condition holds if and only if $t<t_{1}$, where $t_{1}$ is the unique positive solution of the equation $t=3 \tanh (t / 2)$. Consequently $\eta$ is strictly concave on $\left.] 0, t_{1}\right]$ and convex on $\left[t_{1}, \infty[\right.$. Since $t_{1} \simeq 2.5757>2>t_{0}$, it follows that $\eta$ is strictly concave on $\left.] 0, t_{0}\right]$, increasing on $] 0, t_{0}$ ] and decreasing on $\left[t_{0}, \infty[\right.$.

We now prove that $\ell_{c}$ is convex, increasing and continuously differentiable. Since $\ell_{c}(t)=\ell(t)$ for $t \leq t_{0}$, the function $\ell_{c}$ is strictly convex, increasing and continuously differentiable on $\left[0, t_{0}\right]$. Next $\ell_{c}(t)=t-\log t-1+\eta\left(t_{0}\right)$ for $t \geq t_{0}$, which ensures that $\ell_{c}$ is continuous on $\left[t_{0}, \infty\left[\right.\right.$. Hence $\ell_{c}$ is continuous at the point $t_{0}$. Next the right derivative of $\ell_{c}$ at point $t_{0}$ is equal to $1-t_{0}^{-1}$ and the left derivative is equal to $\ell^{\prime}\left(t_{0}\right)$. Since $\eta^{\prime}\left(t_{0}\right)=0, \ell^{\prime}\left(t_{0}\right)=1-t_{0}^{-1}$. Hence $\ell_{c}$ is differentiable at point $t_{0}$. If follows that $\ell_{c}$ is continuously differentiable on $[0, \infty[$. Now the function $t \rightarrow t-\log t-1$ is strictly convex and increasing on $\left[1, \infty\left[\right.\right.$ and $t_{0}>1$. From the above facts, we get that $\ell_{c}$ is continuously differentiable, strictly convex and increasing on $\left[0, \infty\left[\right.\right.$. Furthermore $\ell_{c}^{\prime}$ is a one to one continuous and increasing map from $[0, \infty[$ onto $[0,1[$.

We now prove (a). From the definition of $\ell_{c}, \ell_{c}^{\prime}(t)=\ell^{\prime}(t) \leq \ell^{\prime}\left(t_{0}\right)$ for $t \leq t_{0}$ and $\ell^{\prime}(t)=1-t^{-1}>\ell^{\prime}\left(t_{0}\right)$ for $t>t_{0}$. Hence, for $x \leq \ell^{\prime}\left(t_{0}\right)$ the maximum of $x t-\ell_{c}(t)$ over all positive reals $t$ is reached at $t_{x}=\ell^{\prime-1}(x) \leq t_{0}$. Then $\ell_{c}^{*}(x)=x t_{x}-\ell\left(t_{x}\right)=\ell^{*}(x)$. For $x \geq \ell^{\prime}\left(t_{0}\right)$, the maximum of $x t-\ell_{c}(t)$ over all positive reals $t$ is reached at the unique point $t_{x} \geq t_{0}$ such that $1-t_{x}^{-1}=x$. Then $t_{x}=1 /(1-x)$ and

$$
\ell_{c}^{*}(x)=x t_{x}-\ell_{c}\left(t_{x}\right)=\frac{x}{1-x}-\frac{1}{1-x}+1-\log (1-x)-\eta\left(t_{0}\right)=-\log (1-x)-\eta\left(t_{0}\right)
$$

which completes the proof of Proposition 3.1(a).
To prove (b), we note that, for any $t$ in $\left[0, t_{0}\right], \ell_{c}(t)=\ell(t) \leq t^{2} / 8$, since $\ell^{*}(x) \geq 2 x^{2}$ for any positive $x$. Now, for any $t \geq t_{0}, \ell_{c}(t)=t-\log t-1+\eta\left(t_{0}\right)$. Deriving this equality, we get that $(t / 4)-\ell_{c}^{\prime}(t)=(t-2)^{2} /(4 t) \geq 0$. Consequently $t^{2} / 8-\ell_{c}$ is nondecreasing on $\left[t_{0}, \infty\left[\right.\right.$, whence $t^{2} / 8-\ell_{c}(t) \geq\left(t_{0}^{2} / 8\right)-\ell_{c}\left(t_{0}\right) \geq 0$ for $t \geq t_{0}$. Proposition 3.1(b) holds.

Proof of Theorem 3.2. By definition, $\eta_{c}$ is concave. Hence

$$
\eta_{c}\left(\Delta_{1} t\right)+\eta_{c}\left(\Delta_{2} t\right)+\cdots+\eta_{c}\left(\Delta_{n} t\right) \leq n \eta_{c}\left(A_{n} t\right)
$$

Since $\ell \leq \ell_{c}$,

$$
\ell\left(\Delta_{1} t\right)+\ell\left(\Delta_{2} t\right)+\cdots+\ell\left(\Delta_{n} t\right) \leq n\left(A_{n} t-1-\log t\right)-\log \left(\Delta_{1} \ldots \Delta_{n}\right)+n \eta_{c}\left(A_{n} t\right)
$$

It follows that

$$
\begin{equation*}
\ell\left(\Delta_{1} t\right)+\ell\left(\Delta_{2} t\right)+\cdots+\ell\left(\Delta_{n} t\right) \leq n \log \left(A_{n} / G_{n}\right)+n \ell_{c}\left(A_{n} t\right), \tag{4.13}
\end{equation*}
$$

which, together with Lemma 4.1, implies Theorem 3.2(a). (b) and (c) follow from the usual Chernoff calculation together with Proposition 3.1(a).

## 5 An inequality involving partitions

In this section we are interested in intermediate values of the deviation $x$. In the sketchy Example 3.1, it appears that the McDiarmid diameter $\sigma_{n}$ defined in (1.2) is too big for intermediates values of the deviation. In this section, we introduce a method which minimizes the effect of variations of the values of the individual diameters $\Delta_{1}, \Delta_{2}, \ldots, \Delta_{n}$.
Definition 5.1. A set $\mathcal{P}$ of subsets of $\{1,2, \ldots, n\}$ is called partition of $\{1,2, \ldots, n\}$ iff: (i) for any $I$ in $\mathcal{P}, I$ is nonempty; (ii) for any $I$ and for any $J$ in $\mathcal{P}$, either $I \cap J=\emptyset$ or $I=J$; (iii) $\bigcup_{I \in \mathcal{P}} I=\{1,2, \ldots, n\}$.

We now define the diameter $\sigma(\mathcal{P})$ and the entropy $H(\mathcal{P})$ of a partition $\mathcal{P}$ as follows. Let $|J|$ denote the cardinality of a finite set $J$. We set

$$
\begin{equation*}
D_{J}=\sum_{j \in J} \Delta_{j}, A_{J}=|J|^{-1} D_{J} \quad \text { and } \quad \sigma^{2}(\mathcal{P})=\sum_{J \in \mathcal{P}}|J| A_{J}^{2} \tag{5.1}
\end{equation*}
$$

Let the geometric means $G_{J}$ and the entropy be defined by

$$
\begin{equation*}
G_{J}=\left(\prod_{j \in J} \Delta_{j}\right)^{1 /|J|} \text { and } H(\mathcal{P})=\sum_{J \in \mathcal{P}}|J| \log \left(A_{J} / G_{J}\right) \tag{5.2}
\end{equation*}
$$

The so defined quantities satisfy $\sigma^{2}(\mathcal{P}) \leq \sigma_{n}^{2}$ and $H(\mathcal{P}) \geq 0$. Furthermore $H(\mathcal{P})=0$ if and only if $\sigma^{2}(\mathcal{P})=\sigma_{n}^{2}$.

Theorem 5.1. Let the convex and differentiable function $\ell_{0}$ be defined by

$$
\ell_{0}(t)=t^{2} / 8 \text { for } t \in[0,2] \text { and } \ell_{0}(t)=t-\log t-(3 / 2)+\log 2 \text { for } t \geq 2
$$

Let $Z$ be defined by (1.1). For any positive $t$ and any partition $\mathcal{P}$ of $\{1,2, \ldots, n\}$,

$$
\begin{equation*}
\log \mathbb{E}(\exp (t Z-t \mathbb{E}(Z))) \leq H(\mathcal{P})+\left(D_{n}^{2} / \sigma^{2}(\mathcal{P})\right) \ell_{0}\left(\sigma^{2}(\mathcal{P}) t / D_{n}\right) \tag{a}
\end{equation*}
$$

Consequently, for any $x$ in $[0,1]$,

$$
\begin{equation*}
\mathbb{P}\left(Z-\mathbb{E}(Z) \geq D_{n} x\right) \leq \exp \left(H(\mathcal{P})-\left(D_{n}^{2} / \sigma^{2}(\mathcal{P})\right) \ell_{0}^{*}(x)\right) \tag{b}
\end{equation*}
$$

and, for any positive $y$,

$$
\begin{equation*}
\mathbb{P}\left(Z-\mathbb{E}(Z) \geq D_{n} \ell_{0}^{*-1}\left(D_{n}^{-2} \min _{\mathcal{P}} \sigma^{2}(\mathcal{P})(H(\mathcal{P})+y)\right)\right) \leq e^{-y} \tag{c}
\end{equation*}
$$

Remark 5.1. In Theorem 5.1(c), for small values of $y$, the optimal partition has a small entropy and a large diameter, while, for large values of $y$, the optimal partition has a small diameter and a large entropy.
Remark 5.2. The functions $\ell_{0}^{*}$ and $\ell_{0}^{*-1}$ are explicit. More precisely

$$
\begin{gathered}
\ell_{0}^{*}(x)=2 x^{2} \text { for } x \in[0,1 / 2] \text { and } \ell_{0}^{*}(x)=-\log (1-x)+(1 / 2)-\log 2 \text { for } x \in[1 / 2,1], \\
\quad \ell_{0}^{*-1}(y)=\sqrt{y / 2} \text { for } y \in[0,1 / 2] \text { and } \ell_{0}^{*-1}(y)=1-(\sqrt{e} / 2) e^{-y} \text { for } y \geq 1 / 2 .
\end{gathered}
$$

Example 3.1 (continued). Let $Q$ denote the quantile function of $Z-\mathbb{E}(Z)$. For $p=$ $e^{-9 / 2}$, Theorem 5.1(c) applied with $\mathcal{P}=\{[1,13],[14,100]\}$ (the optimal partition) yields $Q(p) \leq 62.18$. The McDiarmid inequality (1.3) yields $Q(p) \leq 75$, and Theorem 3.2 yields $Q(p) \leq 64.93$. For small values of $p$, the optimal partition is $\mathcal{P}=\{[1,100]\}$. In this case Theorem 5.1 is less efficient than Theorem 3.2, since $\ell_{0}^{*-1}(y)>\ell_{c}^{*-1}(y)$. For example, let $q=\mathbb{P}(Z-\mathbb{E}(Z) \geq 75)$. Theorem 5.1(b) yields $q \leq 3.010^{-7}$ instead of $q \leq 2.710^{-8}$ with Theorem 3.2. Recall that (1.3) yields $q \leq 1.110^{-2}$.

Proof of Theorem 5.1. By Lemma 4.1 together with (4.13),

$$
\log \mathbb{E}(\exp (t Z-t \mathbb{E}(Z))) \leq \sum_{J \in \mathcal{P}} \sum_{j \in J} \ell\left(\Delta_{j} t\right) \leq H(\mathcal{P})+\sum_{J \in \mathcal{P}}|J| \ell_{c}\left(A_{J} t\right)
$$

Now $\ell_{c}(t) \leq \min \left(t^{2} / 8, \eta\left(t_{0}\right)+t-\log t-1\right) \leq \ell_{0}(t)$ for any positive $t$. Hence

$$
\begin{equation*}
\log \mathbb{E}(\exp (t Z-t \mathbb{E}(Z))) \leq H(\mathcal{P})+\sum_{J \in \mathcal{P}}|J| \ell_{0}\left(A_{J} t\right) \tag{5.3}
\end{equation*}
$$

To complete the proof of Theorem 5.1, we proceed exactly as in the proof of Theorem 3.1: since $\ell_{0}(0)=0$,

$$
\begin{equation*}
\sum_{J \in \mathcal{P}}|J| \ell_{0}\left(A_{J} t\right)=\int_{0}^{t}\left(\sum_{J \in \mathcal{P}} D_{J} \ell_{0}^{\prime}\left(A_{J} u\right)\right) d u \tag{5.4}
\end{equation*}
$$

## On McDiarmid's concentration inequality

Now $\ell_{0}^{\prime}(t)=t / 4$ for $t \leq 2$ and $\ell_{0}^{\prime}(t)=1-(1 / t)$ for $t \geq 2$, which ensures that $\ell_{0}^{\prime}$ is continuous and increasing. $\ell_{0}^{\prime \prime}(t)=1 / 4$ for $t<2$ and $\ell^{\prime \prime}(0)=t^{-2}$ for $t>2$, which ensures that $\lim _{t \downarrow 2} \ell_{0}^{\prime \prime}(t)=1 / 4$. Hence, by L'Hospital's rule, $\ell_{0}^{\prime}$ is differentiable at point 2, and $\ell_{0}^{\prime \prime}(2)=4$. Consequently $\ell_{0}^{\prime \prime}$ is continuous and nonincreasing, which ensures that $\ell_{0}^{\prime}$ is concave. It follows that

$$
\sum_{J \in \mathcal{P}} D_{J} \ell_{0}^{\prime}\left(A_{J} u\right) \leq D_{n} \ell_{0}^{\prime}\left(\sigma^{2}(\mathcal{P}) u / D_{n}\right)
$$

Integrating this inequality, we then get that

$$
\begin{equation*}
\int_{0}^{t}\left(\sum_{J \in \mathcal{P}} D_{J} \ell_{0}^{\prime}\left(A_{J} u\right)\right) d u \leq\left(D_{n}^{2} / \sigma^{2}(\mathcal{P})\right) \ell_{0}\left(\sigma^{2}(\mathcal{P}) t / D_{n}\right) \tag{5.5}
\end{equation*}
$$

which, together with (5.3) and (5.4), implies Theorem 5.1(a). Theorem 5.1(b) follows from the usual Chernoff calculation and Theorem 5.1(c) is an immediate consequence of Theorem 5.1(b).
