

STABILITY OF JUNGCK-TYPE ITERATIVE PROCEDURES

S. L. SINGH, CHARU BHATNAGAR, AND S. N. MISHRA

Received 2 December 2004 and in revised form 9 September 2005

We introduce and discuss the stability of Jungck and Jungck-Mann iterative procedures for a pair of Jungck-Osilike-type maps on an arbitrary set with values in a metric or linear metric space.

1. Introduction

Let (X, d) be a metric space and $T : X \rightarrow X$. Several physical problems, expressed as a fixed point equation $Tx = x$, are solved by approximating a sequence $\{x_n\} \subset X$ generated by an iterative procedure $f(T, x_n)$. Let the sequence $\{x_n\}$ converge to a fixed point of T . The iterative procedure $f(T, x_n)$ is considered numerically stable if and only if a sequence $\{y_n\} \subset X$ approximatively close to $\{x_n\}$ converges to the desired solution of the equation $Tx = x$. This kind of study in R^1 was initiated by Urabe [32] during the middle of the last century (see also, Collatz [3] and Ortega and Rheinboldt [17]). However, a formal definition of the stability of general iterative procedures is due to Harder and Hicks [7, 8] (cf. definition below). Ostrowski [20] appears to be the first to discuss the stability of iterative procedures on metric spaces. Due to its increasing importance in computational mathematics, especially due to the revolution in computer programming, the stability theory has extensively been studied by various authors (see, e.g., Berinde [1], Czerwik et al. [4], Istrăţescu [9], Jachymski [11], Matkowski and Singh [15], Osilike [18, 19], Rus et al. [27], Rhoades [24, 25], and several references of [1, 27]). However, in all these references cited above, special cases of the following fundamental iterative procedure

$$x_{n+1} = f(T, x_n), \quad n = 0, 1, \dots, \quad (\text{HH})$$

have been studied. As discussed by Harder [6], Harder and Hicks [7, 8], and Berinde [1], the study of stability of iterative procedures is both of theoretical and numerical interest. We introduce the notion of the stability of the iterative procedure (S-HH) (see below) for a pair of self-maps and develop the theory for this general procedure. Notice that (S-HH) reduces to (HH) when $Y = X$ and $S = id$, the identity map on X . It may be of interest to note that, besides including the Jungck iterations (see below), (S-HH) includes the well-known Picard, Mann, and a host of other iterative procedures.

2. Preliminaries

Throughout the paper, let Y be an arbitrary nonempty set and (X, d) a metric space. Let $S, T : Y \rightarrow X$ and $T(Y) \subseteq S(Y)$. For any $x_0 \in Y$, consider

$$Sx_{n+1} = f(T, x_n), \quad n = 0, 1, \dots \quad (\text{S-HH})$$

For $Y = X$ and $f(T, x_n) = Tx_n$, the iterative procedure (S-HH) yields the Jungck iterations (or J-iterations in brief), namely, $Sx_{n+1} = Tx_n$, $n = 0, 1, \dots$. This procedure was essentially introduced by Jungck [12], and it becomes the Picard iterative procedure when $S = id$, the identity map on X . Jungck [12] showed that the maps S and T satisfying

$$d(Tx, Ty) \leq kd(Sx, Sy), \quad 0 \leq k < 1, \quad (\text{J})$$

for all $x, y \in X$ have a unique common fixed point in complete X , provided that S and T are commuting, $T(X) \subseteq S(X)$, and S is continuous. However, the following significantly improved version of this result is generally called the Jungck contraction principle.

THEOREM JS [30]. *Let $S, T : Y \rightarrow X$ satisfy (J) for all $x, y \in Y$. If $T(Y) \subseteq S(Y)$ and $S(Y)$ or $T(Y)$ is a complete subspace of X , then S and T have a coincidence. Indeed, for any x_0 in Y , there exists a sequence $\{x_n\}$ in Y such that*

- (a) $Sx_{n+1} = Tx_n$, $n = 0, 1, \dots$,
- (b) $\{Sx_n\}$ converges to Sz for some z in Y , and $Sz = Tz$, that is, S and T have a coincidence at z .

Further, if $Y = X$ and S, T commute (just) at z , then S and T have a unique common fixed point.

A pair of maps S, T satisfying (J) is generally termed as Jungck contraction or J-contraction (cf. Singh [30] and Tivari and Singh [31]). We remark that neither Theorem JS nor any of all the existing generalizations of Jungck's common fixed point theorem [12] says nothing about the convergence of $\{x_n\}$ when Y is a metric space or $Y = X$ (see also [5, 10, 13, 16, 22, 27, 28, 29, 30, 31] and references thereof). Further, if $z_i \in Y$ are such that $Sz_i = Tz_i$, $i = 1, 2, \dots, n$, then $Sz_j = Tz_j$, $i, j = 1, 2, \dots, n$, that is, under the conditions of Theorem JS, S and T may have many coincidence points, but the coincidence values are the same (cf. Singh [29]). For various applications of J-iterations to numerical problems, one may refer to [30] (see also [16]). For practical applications in numerical computations and other situations, characterization of J-contractivity for real-valued functions is of practical importance. So, first we present the following result, wherein $[a, b]$ (resp., $]a, b[$) stands for the closed (resp., open) interval and $S'x$ for the derivative of S at x .

THEOREM S [30]. *Let $S, T : [a, b] \rightarrow [a, b]$ be differentiable with $Sa \neq Sb$. Let $T'x$ and $S'x$ be not both equal to zero for any $x \in]a, b[$. The pair (S, T) is a J-contraction of $[a, b]$ if and only if there exists a positive number $q < 1$ such that $|T'y| \leq q|S'y|$ for all $y \in]a, b[$.*

Theorem JS, the foregoing discussion, and the fundamental work of Harder and Hicks [7, 8] motivate the following definition.

Definition 2.1. Let $S, T : Y \rightarrow X$, $T(Y) \subseteq S(Y)$, and z a coincidence point of T and S , that is, $Sz = Tz = p$ (say). For any $x_0 \in Y$, let the sequence $\{Sx_n\}$, generated by the iterative procedure (S-HH), converge to p . Let $\{Sy_n\} \subset X$ be an arbitrary sequence, and set $\varepsilon_n = d(Sy_{n+1}, f(T, y_n))$, $n = 0, 1, 2, \dots$. Then the iterative procedure $f(T, x_n)$ will be called (S, T) -stable if and only if $\lim_n \varepsilon_n = 0$ implies that $\lim_n Sy_n = p$.

This definition reduces to that of the stability of iterative procedure (HH) due to Harder and Hicks [7, 8] when $Y = X$ and $S = id$. Further, as regards the construction of the sequences $\{Sx_n\}$ and $\{x_n\}$ under the procedure (S-HH), we may calculate $a_1 = f(T, x_0)$ and then may proceed to solve the equation $Sx_1 = a_1$. We remark that if the map S is not one-one, then we have multiple choices for x_1 as we have to find an $x_1 \in S^{-1}a_1$. So, one might suspect complications in writing computer programs for solving equations under the general procedure (S-HH) or, in particular, under the J-iterations (cf. Theorem JS (a)). The suspicion is blown immediately by the fact that, whatever the choice of x_1 (in $S^{-1}a_1$) is, Sx_1 always equals a_1 . For this kind of computer programs intended to solve numerical problems under J-iterations, one may refer to [30]. However, in actual practice, the choice of x_1 is approximative and Sx_1 is not exactly equal to a_1 . So, in general, instead of getting an exact sequence $\{Sx_n\}$, we get an approximative sequence $\{Sy_n\}$, and this is the main problem that stability plays a crucial role in actual numerical computations.

For several examples discussing the practical aspect and theoretical importance of the stability when $Y = X$ and S is the identity operator on X in the above definition, one may refer to Berinde [1] and Harder and Hicks [7, 8].

3. Main results

First, we present a basic result for the stability of J-iterations.

THEOREM 3.1. *Let S and T be maps on an arbitrary set Y with values in X such that $T(Y) \subseteq S(Y)$, and $S(Y)$ or $T(Y)$ is a complete subspace of X . Let z be a coincidence point of T and S , that is, $Sz = Tz = p$ (say). Let $x_0 \in Y$ and let the sequence $\{Sx_n\}$, generated by $Sx_{n+1} = Tx_n$, $n = 0, 1, \dots$, converge to p . Let $\{Sy_n\} \subset X$ and define $\varepsilon_n = d(Sy_{n+1}, Ty_n)$, $n = 0, 1, \dots$. If the pair (S, T) is a J-contraction, that is, S and T satisfy (J) for all $x, y \in Y$, then*

$$(I) \quad d(p, Sy_{n+1}) \leq d(p, Sx_{n+1}) + k^{n+1}d(Sx_0, Sy_0) + \sum_{i=0}^n k^{n-i}\varepsilon_i;$$

further,

$$(II) \quad \lim_n Sy_n = p \text{ if and only if } \lim_n \varepsilon_n = 0.$$

Notice that Theorem 3.1 is Theorem 3.4 with $a = k$ and $L = 0$. However, we give a blend of the proof of Theorem 3.1.

Proof. By the triangle inequality and the condition (J),

$$\begin{aligned} d(p, Sy_{n+1}) &\leq d(p, Sx_{n+1}) + kd(Sx_n, Sy_n) + \varepsilon_n \\ &\leq d(p, Sx_{n+1}) + k[d(Tx_{n-1}, Ty_{n-1}) + d(Ty_{n-1}, Sy_n)] + \varepsilon_n. \end{aligned} \quad (3.1)$$

Therefore,

$$d(p, Sy_{n+1}) \leq d(p, Sx_{n+1}) + k^2d(Sx_{n-1}, Sy_{n-1}) + k\varepsilon_{n-1} + \varepsilon_n. \quad (3.2)$$

This process, when repeated $n - 1$ times, yields (I).

To prove (II), first suppose that $\lim_n S y_n = p$. Then,

$$\begin{aligned} \varepsilon_n &= d(Sy_{n+1}, Ty_n) \\ &\leq d(Sy_{n+1}, Sx_{n+1}) + d(Tx_n, Ty_n) \\ &\leq d(Sy_{n+1}, Sx_{n+1}) + kd(Sx_n, Sy_n) \rightarrow 0, \quad \text{as } n \rightarrow \infty. \end{aligned} \tag{3.3}$$

Now, suppose that $\lim_n \varepsilon_n = 0$.

Let A denote the lower triangular matrix with entries $a_{ni} = k^{n-i}$. Then, $\lim_n a_{ni} = 0$ for each i and $\sum_{i=0}^n a_{ni} = (1 - k^{n+1})/(1 - k) \rightarrow 1/(1 - k)$ as $n \rightarrow \infty$. Therefore, A is multiplicative, that is, for any convergent sequence $\{s_n\}$, $\lim_n A(s_n) := \{1/(1 - k)\} \lim_n s_n$ (cf. Rhoades [25, page 692]). Since $\lim_n \varepsilon_n = 0$, $\lim_n \sum_{i=0}^n k^{n-i} \varepsilon_i = 0$. Also, $\lim_n Sx_n = p$ implies that $\lim_n d(p, Sx_{n+1}) = 0$. This completes the proof. \square

The following classical result is obtained from Theorem 3.1 with $Y = X$ and $S = id$.

COROLLARY 3.2 (Ostrowski [20]). *Let (X, d) be a complete metric space and $T : X \rightarrow X$. Let $p \in X$ be a fixed point of T . Let $x_0 \in X$ and $x_{n+1} = Tx_n$ for $n = 0, 1, 2, \dots$. Suppose that $\{y_n\} \subset X$, $\varepsilon_n = d(y_{n+1}, Ty_n)$. If T is the Banach contraction on X with contraction constant k , then*

$$d(p, y_{n+1}) \leq d(p, x_{n+1}) + k^{n+1}d(x_0, y_0) + \sum_{i=0}^n k^{n-i} \varepsilon_i. \tag{3.4}$$

Also, $\lim_n y_n = p$ if and only if $\lim_n \varepsilon_n = 0$.

We remark that deriving an inspiration from Park and Bae [21] and using Corollary 3.2, one may have an alternative proof of Theorem 3.1. We give a sketch of the same.

Another proof. With the notations of Theorem 3.1, let $a_n = Sx_n$ and $z_n = Sy_n$. Then, $x_n \in S^{-1}a_n$ and $y_n \in S^{-1}z_n$, so that we can write $a_{n+1} = Tx_n \in T(S^{-1}a_n)$. As a matter of fact, for every $u \in S(Y)$, the set $T(S^{-1}u)$ is a singleton. Indeed, for $a, b \in T(S^{-1}u)$, there exist $\alpha, \beta \in S^{-1}u$ such that $a = T\alpha$, $b = T\beta$, and $S\alpha = u = S\beta$. Therefore,

$$d(a, b) = d(T\alpha, T\beta) \leq kd(S\alpha, S\beta) = 0 \implies a = b. \tag{3.5}$$

Hence, if we define a map $F : S(Y) \rightarrow T(Y) \subseteq S(Y)$ such that $F(u) = T(S^{-1}u)$, then F is well defined. Further, as above, for $a \in T(S^{-1}u)$ and $b \in T(S^{-1}v)$,

$$d(Fu, Fv) = d(a, b) = d(T\alpha, T\beta) \leq kd(S\alpha, S\beta) = kd(u, v). \tag{3.6}$$

Consequently, F is a Banach contraction. Thus, the procedure (S-HH) can be rewritten as

$$a_{n+1} = Fa_n \tag{3.7}$$

which is of the form (HH). Moreover,

$$\varepsilon_n = d(Sy_{n+1}, Ty_n) = d(z_{n+1}, Fz_n). \tag{3.8}$$

All these show that the conclusions of Theorem 3.1 follow from Corollary 3.2. \square

We remark that, following the above construction, one may derive the conclusions (a) and (b) of Theorem JS from the Banach's fixed point theorem.

Consider the following conditions for $S, T : Y \rightarrow X$, $x, y \in Y$, and for some $k \in (0, 1)$: we give a comparison of these conditions;

$$d(Tx, Ty) \leq k \max \left\{ d(Sx, Sy), d(Sx, Tx), d(Sy, Ty), \frac{[d(Sx, Ty) + d(Sy, Tx)]}{2} \right\}, \quad (S)$$

$$d(Tx, Ty) \leq k \max \left\{ d(Sx, Sy), \frac{[d(Sx, Tx) + d(Sy, Ty)]}{2}, d(Sx, Ty), d(Sy, Tx) \right\}, \quad (R)$$

$$d(Tx, Ty) \leq k \max \{d(Sx, Sy), d(Sx, Tx), d(Sy, Ty), d(Sx, Ty), d(Sy, Tx)\}, \quad (RDN)$$

$$d(Tx, Ty) \leq ad(Sx, Sy) + Ld(Sx, Tx), \quad a \in (0, 1), L \geq 0. \quad (JO)$$

PROPOSITION 3.3. (i) $(J) \Rightarrow (S) \Rightarrow (RDN)$; (ii) $(J) \Rightarrow (R) \Rightarrow (RDN)$; (iii) (S) and (R) are independent; (iv) $(R) \Rightarrow (JO)$; (v) (S) and (JO) are independent; (vi) (RDN) and (JO) are independent; (vii) reverse implications of (i), (ii), and (iv) are not true.

In view of rigorous comparisons of contracting maps presented by Rhoades [23], it is easy to see (i), (ii), (iv), and (vii). The condition (JO) with $Y = X$ and $S = id$ is discussed by Osilike [18], and the same conclusion makes (vi) evident (see also Berinde [1, pages 137 and 153]). Proof of (v) is akin to that of (vi).

Theorem JS with (J) replaced by (R) is true (cf. Singh [29]). We remark that maps S and T satisfying (JO) need not have a coincidence point. For example, if $Y = X = \{1, 2\}$, d is the discrete metric, $T1 = 2$, $T2 = 1$, and $Sx = x$ for $x \in X$, then (JO) holds for all $x, y \in Y = X$ with $a = L = 1/2$ (see also Osilike [18] and Berinde [1, page 137]). Further, the condition (S) was first studied by Singh [28], while (RDN), as a generalization of (S), was studied independently by Ranganathan [22] and Das and Naik [5]. The stability of (R) with $Y = X$ and $S = id$ has been studied by Rhoades [25] (see Corollary 3.6 below). It may be mentioned that (RDN) with $Y = X$ and $S = id$ is the most general contraction condition due to Ćirić [2] (see [5]). Osilike's very general stability result [18] is obtained under the condition (JO) with $Y = X$ and $S = id$ (see Rhoades and Saliga [26, page 204]).

We now present general stability results for maps satisfying (JO).

THEOREM 3.4. Let S and T be maps on an arbitrary set Y with values in X such that $T(Y) \subseteq S(Y)$, and $S(Y)$ or $T(Y)$ is a complete subspace of X . Let z be a coincidence point of T and S , that is, $Sz = Tz = p$ (say). Let $x_0 \in Y$ and the sequence $\{Sx_n\}$, generated by $Sx_{n+1} = Tx_n$, $n = 0, 1, \dots$, converge to p . Let $\{Sy_n\} \subset X$ and define $\varepsilon_n = d(Sy_{n+1}, Ty_n)$, $n = 0, 1, \dots$. If (S, T) satisfies (JO) for all $x, y \in Y$, then

(III) $d(p, Sy_{n+1}) \leq d(p, Sx_{n+1}) + L \sum_{i=0}^n a^{n-i} d(Sx_i, Tx_i) + a^{n+1} d(Sx_0, Sy_0) + \sum_{i=0}^n a^{n-i} \varepsilon_i$ further,

(IV) $\lim_n Sy_n = p$ if and only if $\lim_n \varepsilon_n = 0$.

Proof. It may be completed following the proof of Theorem 3.5. □

Notice that Theorem 3.4 reduces to Theorem 3.1 when $L = 0$. Also, the general stability result, given by Osilike [18], is derivable from Theorem 3.4 with $Y = X$ and $S = id$.

In all that follows, X is a normed linear space and d stands for the metric induced by the norm of X . Consider the iterative procedure

$$Sx_{n+1} = (1 - \alpha_n)Sx_n + \alpha_n f(T, x_n), \tag{***}$$

where $\{\alpha_n\}$ satisfies (i) $\alpha_0=1$, (ii) $0 \leq \alpha_n \leq 1$ for $n > 0$, (iii) $\sum \alpha_n = \infty$, and (iv) $\sum_{j=0}^n \alpha_j \prod_{i=j+1}^n \{1 - \alpha_i + \alpha_i\}$ converges.

We will call it Jungck-Mann iterations or simply JM-iterations. Taking $Y = X$, $S = id$, and $f(T, x_n) = Tx_n$, (***) reduces to the following:

$$x_{n+1} = (1 - \alpha_n)x_n + \alpha_n Tx_n, \tag{M}$$

with $\{\alpha_n\}$ satisfying (i)–(iv). This process was introduced by Mann [14] and has been found very useful in approximating solutions of fixed point equations (see, e.g., [1, 24, 25, 26, 27]).

Now, in the next theorem, we prove that the JM-iterative procedure is (S, T) -stable for maps S and T satisfying (JO).

THEOREM 3.5. *Let S and T be maps on an arbitrary set Y with values in X such that $T(Y) \subseteq S(Y)$, and $S(Y)$ or $T(Y)$ is a complete subspace of X . Let z be a coincidence point of T and S , that is, $Sz = Tz = p$ (say). Let $x_0 \in Y$ and the sequence $\{Sx_n\}$, generated by $Sx_{n+1} = (1 - \alpha_n)Sx_n + \alpha_n Tx_n$, $n = 0, 1, \dots$, with $\{\alpha_n\}$ satisfying (i)–(iv), converge to p . Let $\{Sy_n\} \subset X$ and define*

$$\epsilon_n = d(Sy_{n+1}, (1 - \alpha_n)Sy_n + \alpha_n Ty_n), \quad n = 0, 1, \dots \tag{3.9}$$

If the pair (S, T) satisfies (JO) for all $x, y \in Y$, then

(V)

$$d(p, Sy_{n+1}) \leq d(p, Sx_{n+1}) + L \sum_{j=0}^n \alpha_j \prod_{i=j+1}^n (1 - \alpha_i + \alpha_i) d(Sx_i, Tx_i) + \prod_{i=0}^n (1 - \alpha_i + \alpha_i) d(Sx_0, Sy_0) + \sum_{j=0}^n \alpha_j \prod_{i=j+1}^n (1 - \alpha_i + \alpha_i) \epsilon_j, \tag{3.10}$$

where the product is 1 when $j = n$. Further,

(VI) $\lim_n Sy_n = p$ if and only if $\lim_n \epsilon_n = 0$.

Proof. By the triangle inequality, (***) and (JO),

$$\begin{aligned}
 d(p, Sy_{n+1}) &\leq d(p, Sx_{n+1}) + d((1 - \alpha_n)Sx_n + \alpha_nTx_n, (1 - \alpha_n)Sy_n + \alpha_nTy_n) \\
 &\quad + d((1 - \alpha_n)Sy_n + \alpha_nTy_n, Sy_{n+1}) \\
 &\leq d(p, Sx_{n+1}) + (1 - \alpha_n)d(Sx_n, Sy_n) + \alpha_nd(Tx_n, Ty_n) + \varepsilon_n \\
 &\leq d(p, Sx_{n+1}) + (1 - \alpha_n)d(Sx_n, Sy_n) + \alpha_n[ad(Sx_n, Sy_n) + Ld(Sx_n, Tx_n)] + \varepsilon_n \\
 &\leq d(p, Sx_{n+1}) + (1 - \alpha_n + a\alpha_n)d(Sx_n, Sy_n) + \alpha_nLd(Sx_n, Tx_n) + \varepsilon_n.
 \end{aligned}
 \tag{3.11}$$

Also,

$$\begin{aligned}
 d(Sx_n, Sy_n) &\leq d((1 - \alpha_{n-1})Sx_{n-1} + \alpha_{n-1}Tx_{n-1}, (1 - \alpha_{n-1})Sy_{n-1} + \alpha_{n-1}Ty_{n-1}) \\
 &\quad + d((1 - \alpha_{n-1})Sy_{n-1} + \alpha_{n-1}Ty_{n-1}, Sy_n) \\
 &\leq (1 - \alpha_{n-1})d(Sx_{n-1}, Sy_{n-1}) + \alpha_{n-1}d(Tx_{n-1}, Ty_{n-1}) + \varepsilon_{n-1} \\
 &\leq (1 - \alpha_{n-1})d(Sx_{n-1}, Sy_{n-1}) \\
 &\quad + \alpha_{n-1}[ad(Sx_{n-1}, Sy_{n-1}) + Ld(Sx_{n-1}, Tx_{n-1})] + \varepsilon_{n-1} \\
 &\leq (1 - \alpha_{n-1} + a\alpha_{n-1})d(Sx_{n-1}, Sy_{n-1}) + \alpha_{n-1}Ld(Sx_{n-1}, Tx_{n-1}) + \varepsilon_{n-1}.
 \end{aligned}
 \tag{3.12}$$

Therefore,

$$\begin{aligned}
 d(p, Sy_{n+1}) &\leq d(p, Sx_{n+1}) + (1 - \alpha_n + a\alpha_n)(1 - \alpha_{n-1} + a\alpha_{n-1})d(Sx_{n-1}, Sy_{n-1}) \\
 &\quad + (1 - \alpha_n + a\alpha_n)\alpha_{n-1}Ld(Sx_{n-1}, Tx_{n-1}) + \alpha_nLd(Sx_n, Tx_n) \\
 &\quad + (1 - \alpha_n + a\alpha_n)\varepsilon_{n-1} + \varepsilon_n.
 \end{aligned}
 \tag{3.13}$$

This process, when repeated $n - 1$ times, yields (V).

To prove (VI), suppose that $\lim_n Sy_n = p$. Then,

$$\begin{aligned}
 \varepsilon_n &= d(Sy_{n+1}, (1 - \alpha_n)Sy_n + \alpha_nTy_n) \\
 &\leq d(Sy_{n+1}, p) + (1 - \alpha_n)d(p, Sy_n) + \alpha_nd(p, Ty_n) \\
 &\leq d(Sy_{n+1}, p) + (1 - \alpha_n)d(p, Sy_n) + \alpha_nd(Tp, Ty_n) \\
 &\leq d(Sy_{n+1}, p) + (1 - \alpha_n)d(p, Sy_n) + \alpha_n[ad(Sp, Sy_n) + Ld(Sp, Tp)] \longrightarrow 0, \quad \text{as } n \longrightarrow \infty.
 \end{aligned}
 \tag{3.14}$$

Now, suppose that $\lim_n \varepsilon_n = 0$. Let A denote the lower triangular matrix with entries

$$b_{nj} = \alpha_j \prod_{i=j+1}^n (1 - \alpha_i + a\alpha_i).
 \tag{3.15}$$

Hence, the condition (iii) implies that this product diverges. Hence, $\lim_n b_{nj} = 0$ for each j . Now, (iv) implies that the limit of the row sum exists. Therefore, A is multiplicative.

Also, $\lim_n Sx_n = p$ implies that $\lim_n d(Sx_n, Tx_n) = 0$. Thus,

$$\lim_n L \sum_{j=0}^n \alpha_j \prod_{i=j+1}^n (1 - \alpha_i + a\alpha_i) d(Sx_i, Tx_i) = 0, \quad \lim_n \sum_{j=0}^n \alpha_j \prod_{i=j+1}^n (1 - \alpha_i + a\alpha_i) \varepsilon_j = 0. \quad (3.16)$$

This completes the proof. \square

The following result may be derived from Theorem 3.5.

COROLLARY 3.6. *In Theorem 3.5 if (JO) is replaced by (R), then (V) and (VI) hold with $a = k$ and $L = k/(1 - k)$.*

We remark that Theorems 3.4 and 3.5 extend and unify several stability results of Harder and Hicks [7, 8], Rhoades [24, 25], and Osilike [18]. In particular, Corollary 3.6 with $Y = X$ and $S = id$ extends several results from [8, 24, 25].

Acknowledgments

The authors thank the referees and Professor Lokenath Debnath for their appreciation, suggestions, and inspiration. Further, the authors owe to one of the referees especially for suggesting the alternative proof of Theorem 3.1.

Special Issue on Intelligent Computational Methods for Financial Engineering

Call for Papers

As a multidisciplinary field, financial engineering is becoming increasingly important in today's economic and financial world, especially in areas such as portfolio management, asset valuation and prediction, fraud detection, and credit risk management. For example, in a credit risk context, the recently approved Basel II guidelines advise financial institutions to build comprehensible credit risk models in order to optimize their capital allocation policy. Computational methods are being intensively studied and applied to improve the quality of the financial decisions that need to be made. Until now, computational methods and models are central to the analysis of economic and financial decisions.

However, more and more researchers have found that the financial environment is not ruled by mathematical distributions or statistical models. In such situations, some attempts have also been made to develop financial engineering models using intelligent computing approaches. For example, an artificial neural network (ANN) is a nonparametric estimation technique which does not make any distributional assumptions regarding the underlying asset. Instead, ANN approach develops a model using sets of unknown parameters and lets the optimization routine seek the best fitting parameters to obtain the desired results. The main aim of this special issue is not to merely illustrate the superior performance of a new intelligent computational method, but also to demonstrate how it can be used effectively in a financial engineering environment to improve and facilitate financial decision making. In this sense, the submissions should especially address how the results of estimated computational models (e.g., ANN, support vector machines, evolutionary algorithm, and fuzzy models) can be used to develop intelligent, easy-to-use, and/or comprehensible computational systems (e.g., decision support systems, agent-based system, and web-based systems)

This special issue will include (but not be limited to) the following topics:

- **Computational methods:** artificial intelligence, neural networks, evolutionary algorithms, fuzzy inference, hybrid learning, ensemble learning, cooperative learning, multiagent learning

- **Application fields:** asset valuation and prediction, asset allocation and portfolio selection, bankruptcy prediction, fraud detection, credit risk management
- **Implementation aspects:** decision support systems, expert systems, information systems, intelligent agents, web service, monitoring, deployment, implementation

Authors should follow the Journal of Applied Mathematics and Decision Sciences manuscript format described at the journal site <http://www.hindawi.com/journals/jamds/>. Prospective authors should submit an electronic copy of their complete manuscript through the journal Manuscript Tracking System at <http://mts.hindawi.com/>, according to the following timetable:

Manuscript Due	December 1, 2008
First Round of Reviews	March 1, 2009
Publication Date	June 1, 2009
