(Received June 10, 1992 and in revised form December 7, 1993)

**ABSTRACT.** The main results of this paper concern radical classes of  $l$ -groups. In the sections 2-3 the relationship between several radical classes of  $l$ -groups are discussed and the characteristic properties for several radical mappings are given. In the sections 5-6 we give nice concrete descriptions of some important radical classes of  $l$ -groups using the structure theorems of a complete  $l$ -group and an Archimedean  $l$ -group.

**KEY WORDS AND PHRASES.** Lattice ordered groups ( $l$ -groups), radical classes of  $l$ -groups, product radical classes, subproduct radical classes, radical mappings.

1992 AMS SUBJECT CLASSIFICATION CODES. 06F15.

**1. INTRODUCTION**

An  $l$ -group  $G$  is a group that is also a lattice such that  $c+a+d \leq c+b+d$  whenever  $a \leq b$  [1]. The theory of  $l$ -groups is as natural as that of rings. But the fact of  $G$  is equipped with two different kind of operations makes the things more complicated. We have more subobjects in the category of  $l$ -groups. An  $l$ -subgroup of an  $l$ -group is both a subgroup and a sublattice. An  $l$ -subgroup  $H$  is convex if  $a, b \in H$  and  $a < g < b$  imply that  $g \in H$ . A normal convex  $l$ -subgroup is called an  $l$ -ideal. A function  $\varphi: G \rightarrow H$  between  $l$ -groups  $G$  and  $H$  is an  $l$ -homomorphism if it is a group and a lattice homomorphism. Let  $\{G_\alpha | \alpha \in A\}$  be a family of  $l$ -groups and  $\prod_{\alpha \in A} G_\alpha$  be their direct product where  $(\dots g_\alpha \dots) \bigwedge_{\alpha \in A} (\dots f_\alpha \dots) = (\dots g_\alpha \bigwedge_{\alpha \in A} f_\alpha \dots)$ . An  $l$ -group  $G$  is said to be a subdirect product of  $G_\alpha$ , in symbols  $G \subseteq' \prod_{\alpha \in A} G_\alpha$ , if  $G$  is an  $l$ -subgroup of  $\prod_{\alpha \in A} G_\alpha$  such that for each  $\alpha \in A$  and each  $g' \in G_\alpha$  there exists  $g \in G$  with the property  $g_\alpha = g'$ . We denote the  $l$ -subgroup of  $\prod_{\alpha \in A} G_\alpha$  consisting of the elements with only finitely many non-zero components by  $\sum_{\alpha \in A} G_\alpha$ . It is called the direct sum of  $\{G_\alpha | \alpha \in A\}$ . An  $l$ -group  $G$  is said to be a completely subdirect product of  $G_\alpha$ , if  $G$  is an  $l$ -subgroup of  $\prod_{\alpha \in A} G_\alpha$  and  $\sum_{\alpha \in A} G_\alpha \subseteq G$ . An  $l$ -group  $G$  is said to be an ideal subdirect product of  $G_\alpha$ , in symbols  $G \subseteq^* \prod_{\alpha \in A} G_\alpha$ , if  $G \subseteq' \prod_{\alpha \in A} G_\alpha$  and  $G$  is an  $l$ -ideal of  $\prod_{\alpha \in A} G_\alpha$ .

Let  $G$  be an  $l$ -group and  $X \subseteq G$ .  $X_G^\perp = \{f \in G | \text{for all } x \in X, |f| \wedge |x| = 0\}$  is called the polar of  $X$  in  $G$  and  $X^{\perp\perp} = (X^\perp)^\perp$  is called the double polar. An  $l$ -subgroup  $H$  of  $G$  is closed in  $G$  if, for all subsets  $\{x_\alpha | \alpha \in A\}$  of  $H$  such that  $a = \bigvee_{\alpha \in A} x_\alpha$  exists in  $G$  we have  $a \in H$ . The order closure  $\overline{H}_G$  of  $H$  in  $G$  is the smallest closed  $l$ -subgroup of  $G$  containing  $H$ . Let  $G_\lambda$  ( $\lambda \in \Lambda$ ) be convex  $l$ -subgroups of  $G$ . The join  $\bigvee_{\lambda \in \Lambda} G_\lambda$  is the smallest convex  $l$ -subgroup of  $G$  containing  $G_\lambda$  ( $\lambda \in \Lambda$ ).

A variety of any type of algebras is an equationally defined class. It is an important area in the study of algebras. In 1935 G. Birkhoff proved that a class of algebras is a variety exactly if it is closed under the formation of subalgebras, products and homomorphic images [2]. In 1937 B. H. Neumann initiated their study for varieties of groups [3, 4]. In the early 70's J. Martinez began the study of varieties of  $l$ -groups [5, 6]. He also studied torsion classes of  $l$ -groups [7, 8, 9]. J. Jakubik studied radical classes of  $l$ -groups [10, 11, 12, 13, 14]. In this paper we give some results in the study for radical classes of  $l$ -groups. We use the standard terminologies and notations of [1, 15, 16].

We can make new  $l$ -groups from some original  $l$ -groups. These structures include:

1. taking  $l$ -subgroups,
- 1'. taking convex  $l$ -subgroups,
2. forming joins of convex  $l$ -subgroups,
3. forming completely subdirect products,
- 3'. forming direct products,
- 3''. forming direct sums,
4. taking  $l$ -homomorphic images,
- 4'. taking complete  $l$ -homomorphic images,
- 4''. taking  $l$ -isomorphic images,
5. forming extensions, that is,  $G$  is an extension of  $A$  by using  $B$  if  $A$  is an  $l$ -ideal of  $G$  and  $B=G/A$ ,
6. taking order closures, that is,  $G$  is an order closure of  $A$  if  $A$  is a convex  $l$ -subgroup of an  $l$ -group  $H$  and  $G=\bar{A}_H$ .
7. taking double polars, that is,  $G$  is a double polar of  $A$  if  $A$  is a convex  $l$ -subgroup of an  $l$ -group  $H$  and  $G=A_H^{\perp\perp}$ .

A family  $\mathcal{U}$  of  $l$ -groups is called a class, if it is closed under some structures. If a class  $\mathcal{U}$  is closed under the structures  $i_1, \dots, i_k$ , we call  $\mathcal{U}$   $i_1 \dots i_k$ -class where  $i_1, \dots, i_k \in \{1, 1', 2, 3, 3', 4, 4', 4'', 5, 6, 7\}$  and  $1 \leq k \leq 7$ . All our classes always assumed to contain along with a given  $l$ -group all its  $l$ -isomorphic images, so we omit the index  $4''$ . Thus, a radical class [10] is a  $1'2$ -class, a quasi-torsion class [17] is a  $1'24'$ -class, a torsion class [7] is a  $1'24$ -class, a  $s$ -closed radical class [18] is a  $12$ -class, a closed-kernel radical class [18] is a  $1'26$ -class, a polar kernel radical class [18] is a  $1'27$ -class, a variety [19] is a  $13'4$ -class.  $1'25$ -class is called a complete (or idempotent) radical class. We call a  $1'23'$ -class ( $1'23$ -class) a product radical class (a subproduct radical class). In this paper we call all  $1'2i_3 \dots i_k$ -classes radical classes where  $i_3, \dots, i_k \in \{3, 3', 3'', 4, 4', 5, 6, 7\}$ .

**2. THE RELATIONSHIP BETWEEN RADICAL CLASSES**

Let  $\mathcal{R}$  be a radical class and  $G$  be an  $l$ -group. Then there exists a largest convex  $l$ -subgroup of  $G$  belonging to  $\mathcal{R}$ . We denote it by  $\mathcal{R}(G)$  and call  $\mathcal{R}(G)$  the  $\mathcal{R}$ -radical of  $G$ . It is invariant under all the  $l$ -automorphisms of  $G$ . Let  $T_{i_1, \dots, i_k}$  be the set of all  $i_1 \dots i_k$ -classes.

LEMMA 2. 1.  $T_{1'2} = T_{1'23''}$ .

Proof. It suffices to prove that each radical class is closed under forming direct sums. Suppose that  $\mathcal{U}$  is a radical class and  $\{G_\alpha | \alpha \in A\} \subseteq \mathcal{U}$ . Consider  $G = \prod_{\alpha \in A} G_\alpha$ . Let  $\bar{G}_\alpha = \{f \in \prod_{\alpha \in A} G_\alpha | \alpha' \neq \alpha \Rightarrow f_{\alpha'} = 0\}$  for each  $\alpha \in A$ . Then  $\sum_{\alpha \in A} G_\alpha \cong \bigvee_{\alpha \in A} {}^{(0)}\bar{G}_\alpha$ . Since  $\mathcal{U}$  is closed under

forming joins of convex  $l$ -subgroups,  $\sum_{\alpha \in A} G_\alpha \in \mathcal{U}$ .

A radical class  $\mathcal{R}$  is said to be a closed-kernel radical class if for any  $l$ -group  $G$   $\mathcal{R}(G)$  is closed [18].

LEMMA 2. 2. A radical class  $\mathcal{R}$  is closed-kernel if and only if  $\mathcal{R}$  is closed under taking order closures.

Proof. Suppose that  $\mathcal{R}$  is a closed-kernel radical class, that is  $\mathcal{R}(G) = \overline{\mathcal{R}(G)}_o$  for any  $l$ -group  $G$ . Let  $G \in \mathcal{R}$  and  $\overline{G}_H$  is an order closure of  $G$  in an  $l$ -group  $H$ ,  $G \subseteq \overline{G}_H$ . Then  $G \subseteq \mathcal{R}(\overline{G}_H) \subseteq \overline{G}_H$ . So  $\mathcal{R}(\overline{G}_H) = \overline{\mathcal{R}(G)}_o = \overline{G}_H$  and  $\overline{G}_H \in \mathcal{R}$ . Conversely, suppose that a radical class  $\mathcal{R}$  is closed under taking order closures. Then for any  $l$ -group  $G$ ,  $\mathcal{R}(G) \in \mathcal{R}$  implies  $\overline{\mathcal{R}(G)}_o \in \mathcal{R}$ . Since  $\mathcal{R}(G)$  is the largest convex  $l$ -subgroup of  $G$  belonging to  $\mathcal{R}$ ,  $\mathcal{R}(G) = \overline{\mathcal{R}(G)}_o$ .

LEMMA 2. 3. Every closed-kernel radical class is also a subproduct radical class, that is  $T_{1'26} = T_{1'23}$ .

Proof. Suppose that  $\mathcal{R}$  is a closed-kernel radical class and  $G$  is a completely subdirect product of  $\{G_\lambda | \lambda \in \Lambda\}$  where  $\{G_\lambda | \lambda \in \Lambda\} \subseteq \mathcal{R}$ , that is

$$\sum_{\lambda \in \Lambda} G_\lambda \subseteq G \subseteq \prod_{\lambda \in \Lambda} G_\lambda.$$

Then  $\mathcal{R}(G) \cap \overline{G}_\lambda = \mathcal{R}(\overline{G}_\lambda) = \overline{G}_\lambda$  and so  $G \supseteq \mathcal{R}(G) \supseteq \overline{G}_\lambda$  for each  $\lambda \in \Lambda$ . Let  $a = (----, a_\lambda, ----) \in G$ . Then

$$a = \bigvee_{\lambda \in \Lambda} {}^{(G)}\bar{a}_\lambda$$

where  $\bar{a}_\lambda = (0, \dots, 0, a_\lambda, 0, \dots, 0) \in \overline{G}_\lambda$  ( $\lambda \in \Lambda$ ). Since  $\mathcal{R}$  is closed-kernel,  $a \in \mathcal{R}(G)$ . Hence  $G = \mathcal{R}(G)$  and  $G \in \mathcal{R}$ .

A radical class  $\mathcal{R}$  is called a polar kernel radical class if  $\mathcal{R} = \mathcal{R}^{\perp\perp}$ , that is  $\mathcal{R}(G) = \mathcal{R}(G)^{\perp\perp}$  for any  $l$ -group  $G$ .

LEMMA 2. 4. A radical class  $\mathcal{R}$  is a polar kernel radical class if and only if  $\mathcal{R}$  is closed under taking double polars.

Proof. Suppose that  $\mathcal{R}$  is a polar kernel radical class. Let  $G \in \mathcal{R}$  and  $G_H^{\perp\perp}$  is a double polar of  $G$  in an  $l$ -group  $H$ . Then  $G \subseteq \mathcal{R}(G_H^{\perp\perp}) \subseteq G_H^{\perp\perp}$  and  $G_H^{\perp\perp} \subseteq \mathcal{R}(G_H^{\perp\perp}) \subseteq G_H^{\perp\perp}$ . So  $\mathcal{R}(G_H^{\perp\perp}) = G_H^{\perp\perp}$  and  $G_H^{\perp\perp} \in \mathcal{R}$ . Conversely, suppose that a radical class  $\mathcal{R}$  is closed under taking double polars. Then for any  $l$ -group  $G$ ,  $\mathcal{R}(G) \in \mathcal{R}$  implies  $\mathcal{R}(G)_o^{\perp\perp} \in \mathcal{R}$ . But  $\mathcal{R}(G)$  is the largest convex  $l$ -subgroup of  $G$  belonging to  $\mathcal{R}$ , so  $\mathcal{R}(G) = \mathcal{R}(G)_o^{\perp\perp}$ .

If  $\mathcal{R}$  and  $\mathcal{F}$  are two 1'2-classes, define the product  $\mathcal{R} \cdot \mathcal{F} = \{G | G/\mathcal{R}(G) \in \mathcal{F}\}$ .  $\mathcal{R} \cdot \mathcal{F}$  is then a 1'2-class. Now similarly to [7] we give a more description of complete 1'2-classes. Let  $\mathcal{F}$  be a 1'2-class and  $\sigma$  be an ordinal number. We define an ascending sequence  $\mathcal{F}, \mathcal{F}^2, \dots, \mathcal{F}^\sigma, \dots$  as follows:

$$\mathcal{F}^\sigma = \begin{cases} \mathcal{F} \cdot \mathcal{F}^{\sigma-1} & \text{if } \sigma \text{ is not a limit ordinal,} \\ \{G | G = \bigcup_{\alpha < \sigma} \mathcal{F}^\alpha(G)\} & \text{if } \sigma \text{ is a limit ordinal.} \end{cases}$$

It is easy to show that  $\mathcal{F}^\sigma$  is a 1'2-class for each ordinal  $\sigma$ . Define

$$\mathcal{F}^* = \bigcup_\sigma \mathcal{F}^\sigma$$

Then we have

PROPOSITION 2. 5. Let  $\mathcal{R}$  be a 1'2-class. Then  $\mathcal{R}^*$  is a complete 1'2-class. It is the smallest complete 1'2-class containing  $\mathcal{R}$ . So,  $\mathcal{R}$  is complete if and only if  $\mathcal{R} = \mathcal{R}^*$ .

The proof of this proposition is similar to the proof of Theorem 1.6 of [7].  $\mathcal{R}^*$  is called the completion of  $\mathcal{R}$ . Similarly to Theorem 1.7 of [7] we have

LEMMA 2.6. Let  $\mathcal{R}$  be a 1'2-class and  $G$  be an  $l$ -group. Then  $\mathcal{R}^*(G) \subseteq \mathcal{R}(G)^{\perp\perp}$ . That is,  $\mathcal{R}^* \subseteq \mathcal{R}^{\perp\perp}$  and  $T_{1'27} \subseteq T_{1'25}$ .

From Proposition 4.4 of [18] we can also see that  $T_{1'27} \subseteq T_{1'25}$ .

Since polars are closed convex  $l$ -subgroups,  $T_{1'267} = T_{1'27}$ . From the above lemmas we get

THEOREM 2.7. For radical classes of  $l$ -groups we have the following relations:

$$\begin{array}{cccccccc}
 & & & & T_{13'4} & & & \\
 & & & & \cap | & & & \\
 & & & & T_{12} & & & \\
 & & & & \cap | & & & \\
 T_{13'4} & \subseteq & T_{1'26} & \subseteq & T_{1'23} & \subseteq & T_{1'22'} & \subseteq & T_{1'2} & \supseteq & T_{1'24'} & \supseteq & T_{1'24} & \supseteq & T_{1'23'4} \\
 & & \cup | & & \cup | & & \cup | & & \cup | & & \cup | & & \cup | & & \\
 & & T_{1'256} & \subseteq & T_{1'235} & \subseteq & T_{1'23'5} & \subseteq & T_{1'25} & \supseteq & T_{1'24'5} & \supseteq & T_{1'245} & & \\
 & & \cup | & & \cup | & & \cup | & & \cup | & & & & & & \\
 T_{1'267} & = & T_{1'237} & = & T_{1'237} & = & T_{1'27} & & & & & & & & & 
 \end{array}$$

COROLLARY 2.8. Any polar kernel radical class is a product radical class and a sub-product radical class.

EXAMPLE 2.9.  $\mathcal{F}_0$ , the class of orthofinite  $l$ -groups, that is  $l$ -groups in which no positive element exceeds an infinite pairwise disjoint set. We can show that  $\mathcal{F}_0$  is a 1'25-class. Suppose  $G \in \mathcal{F}_0$ .  $\mathcal{F}_0$ , that is  $G/\mathcal{F}_0(G) \in \mathcal{F}_0$ . Let  $\{x_\alpha | \alpha \in A\}$  be a pairwise disjoint set of positive elements of  $G$  with an upper bound  $a$ . Then  $A = A_1 \cup A_2$ ,  $A_1 \cap A_2 = \emptyset$  so that  $x_{\alpha_1} \in \mathcal{F}_0(G)$  for  $\alpha_1 \in A_1$  and  $x_{\alpha_2} \notin \mathcal{F}_0(G)$  for  $\alpha_2 \in A_2$ .  $\mathcal{F}_0(G) \in \mathcal{F}_0$  implies  $|A_1|$  is finite. Then we have  $[\mathcal{F}_0(G) + x_\alpha] \wedge [\mathcal{F}_0(G) + x_{\alpha'}] = \mathcal{F}_0(G) + x_\alpha \wedge x_{\alpha'} = \mathcal{F}_0(G)$  for  $\alpha, \alpha' \in A_2$ ,  $\alpha \neq \alpha'$ . So  $\{\mathcal{F}_0(G) + x_\alpha | \alpha \in A_2\}$  is a pairwise disjoint set of positive elements of  $G/\mathcal{F}_0(G)$  with an upper bound  $\mathcal{F}_0(G) + a$ . Hence  $|A_2|$  is also finite. Therefore  $\mathcal{F}_0$  is a complete 1'2-class. But  $\mathcal{F}_0$  is not a 1'23'-class.

EXAMPLE 2.10.  $\mathcal{C}$ , the class of all complete  $l$ -groups, is a 1'23-class, but not a 1'23-class.

EXAMPLE 2.11. Let  $\mathcal{N}$  be the variety of normal-valued  $l$ -groups. Then  $\mathcal{N} \in T_{1'256}$ , but  $\mathcal{N} \not\subseteq T_{1'27}$  by Proposition 4.6 of [18].

### 3. RADICAL MAPPINGS

Let  $\mathcal{R}$  be a 1'2-class and  $G$  be an  $l$ -group. Let  $\mathcal{R}(G)$  be the  $\mathcal{R}$ -radical of  $G$ . The mapping  $G \rightarrow \mathcal{R}$  is called the radical mapping on  $l$ -groups which has the property; if  $A$  is a convex  $l$ -subgroup of  $G$ , then  $\mathcal{R}(A) = A \cap \mathcal{R}(G)$ . Conversely, any mapping  $\varphi$  associating to each  $l$ -group  $G$  an  $l$ -ideal  $\varphi(G)$  of  $G$  and satisfying the above property always define a unique radical class  $\mathcal{R}$  such that  $\mathcal{R}(G) = \varphi(G)$  for each  $l$ -group  $G$  [10]. So a radical class is determined by its radical mapping. The above property is called the characteristic property of a radical mapping. In [7] J. Martinez gave the characteristic properties for torsion radical mapping. In [20] we gave the characteristic properties for product radical mappings as follows.

THEOREM 3.1 (Theorem 2.1 of [20]). A product radical class  $\mathcal{R}$  is uniquely determined by a product radical mapping  $G \rightarrow \mathcal{R}(G)$  which has the characteristic properties; (I) if  $A$  is a convex  $l$ -subgroup of  $G$  then  $\mathcal{R}(A) = A \cap \mathcal{R}(G)$ ; (II) if  $\{G_\lambda | \lambda \in \Lambda\}$  is a family of  $l$ -groups, then  $\mathcal{R}(\prod_{\lambda \in \Lambda} G_\lambda) = \prod_{\lambda \in \Lambda} \mathcal{R}(G_\lambda)$ .

In this section we will prove the characteristic properties for other radical mappings.

**THEOREM 3. 2** A subproduct radical class  $\mathcal{R}$  is uniquely determined by a subproduct radical mapping  $G \rightarrow \mathcal{R}(G)$  which has the characteristic properties: ( I ) if  $A$  is a convex  $l$ -subgroup of  $G$  then  $\mathcal{R}(A) = A \cap \mathcal{R}(G)$ ; ( II ) if  $G$  is a completely subdirect product of  $l$ -groups  $\{G_\lambda | \lambda \in \Lambda\}$  then  $\mathcal{R}(G) = G \cap \prod_{\lambda \in \Lambda} \mathcal{R}(G_\lambda)$ .

Proof. We only prove that the mapping  $G \rightarrow \mathcal{R}(G)$  satisfies the property ( II ). The other parts of proof are similar to the proof of Theorem 2. 1 of [20]. Let  $G$  be a completely subdirect product of  $l$ -groups  $\{G_\lambda | \lambda \in \Lambda\}$ . Put  $\bar{G}_\lambda = \{g \in \prod_{\lambda \in \Lambda} G_\lambda | g_\nu = 0 \text{ for } \nu \neq \lambda\}$  for each  $\lambda \in \Lambda$ . Next, for each  $\lambda \in \Lambda$  and  $x_\lambda \in G_\lambda$  we denote by  $\bar{x}_\lambda$  the element of  $G$  whose  $\lambda$ -coordinate is  $x_\lambda$  and other coordinates are 0. Then the mapping  $\varphi : x_\lambda \rightarrow \bar{x}_\lambda$  is an isomorphism of  $G_\lambda$  onto  $\bar{G}_\lambda$ . Hence  $\varphi(\mathcal{R}(G_\lambda)) = \mathcal{R}(\bar{G}_\lambda)$ .

a) For each  $\lambda \in \Lambda$ ,  $\mathcal{R}(G_\lambda)$  belongs to  $\mathcal{R}$ . Put  $H = G \cap \prod_{\lambda \in \Lambda} \mathcal{R}(G_\lambda)$ . Since  $H$  is a completely subdirect product of the system  $\{\mathcal{R}(G_\lambda) | \lambda \in \Lambda\}$ , we obtain that  $H \in \mathcal{R}$ . Thus  $H \subseteq \mathcal{R}(G)$ .

b) For proving that  $\mathcal{R}(G) \subseteq H$  it suffices to verify that  $\mathcal{R}(G)^+ \subseteq H^+$ . Let  $x \in \mathcal{R}(G)^+$ . For each  $\lambda \in \Lambda$  let  $x_\lambda$  be the coordinate of  $x$  in  $G_\lambda$ . By way of contradiction, suppose that  $x \notin H$ . Hence there is  $\lambda \in \Lambda$  with  $x_\lambda \notin \mathcal{R}(G_\lambda)$ . In view of the isomorphism  $\varphi$ ,  $\bar{x}_\lambda \notin \mathcal{R}(\bar{G}_\lambda)$ . But  $\mathcal{R}(\bar{G}_\lambda) = \mathcal{R}(G) \cap \bar{G}_\lambda$ , hence  $\bar{x}_\lambda \notin \mathcal{R}(G)$ . We have  $0 \leq \bar{x}_\lambda \leq x$  and this implies that  $\bar{x}_\lambda \in \mathcal{R}(G)$ , which is a contradiction.

The proof of the following theorem is left to the reader.

**THEOREM 3. 3** A complete radical class  $\mathcal{R}_{1'25}$  is uniquely determined by a complete radical mapping  $G \rightarrow \mathcal{R}_{1'25}(G)$  which has the characteristic properties: ( I ) if  $A$  is a convex  $l$ -subgroup of  $G$  then  $\mathcal{R}_{1'25}(A) = A \cap \mathcal{R}_{1'25}(G)$ ; ( II ) for any  $l$ -group  $G$   $\mathcal{R}_{1'25}(G/\mathcal{R}_{1'25}(G)) = 0$ .

Form Theorem 3. 1, Theorem 3. 2 and Theorem 3. 3 we get the following theorems.

**THEOREM 3. 4.** A complete product radical class  $\mathcal{R}_{1'23'5}$  is uniquely determined by a complete product radical mapping  $G \rightarrow \mathcal{R}_{1'23'5}(G)$  which has the characteristic properties: ( I ) if  $A$  is a convex  $l$ -subgroup of  $G$  then  $\mathcal{R}_{1'23'5}(A) = A \cap \mathcal{R}_{1'23'5}(G)$ , ( II ) if  $\{G_\lambda | \lambda \in \Lambda\}$  is a family of  $l$ -groups then  $\mathcal{R}_{1'23'5}(\prod_{\lambda \in \Lambda} G_\lambda) = \prod_{\lambda \in \Lambda} \mathcal{R}_{1'23'5}(G_\lambda)$ , ( III ) for any  $l$ -group  $G$   $\mathcal{R}_{1'23'5}(G/\mathcal{R}_{1'23'5}(G)) = 0$ .

**THEOREM 3. 5.** A complete subproduct radical class  $\mathcal{R}_{1'235}$  is uniquely determined by a complete subproduct radical mapping  $G \rightarrow \mathcal{R}_{1'235}(G)$  which has the characteristic properties: ( I ) if  $A$  is a convex  $l$ -subgroup of  $G$  then  $\mathcal{R}_{1'235}(A) = A \cap \mathcal{R}_{1'235}(G)$ ; ( II ) if  $G$  is a completely subdirect product of  $\{G_\lambda | \lambda \in \Lambda\}$  then  $\mathcal{R}_{1'235}(G) = G \cap \prod_{\lambda \in \Lambda} \mathcal{R}_{1'235}(G_\lambda)$ ; ( III ) for any  $l$ -group  $G$   $\mathcal{R}_{1'235}(G/\mathcal{R}_{1'235}(G)) = 0$ .

#### 4. THE STRUCTURE OF A COMPLETE $l$ -GROUP AND ARCHIMEDEAN $l$ -GROUP

In order to give concrete descriptions of some important radical classes we need to know the structure of a complete  $l$ -group and an Archimedean  $l$ -group. First we introduce some concepts. Let  $G$  be an  $l$ -group. We denote by  $vG$  the least cardinal  $\alpha$  such that  $|A| \leq \alpha$  for each bounded disjoint subset  $A$  of  $G$ , where  $|A|$  denotes the cardinal of  $A$ .  $G$  is said to be  $v$ -homogeneous of  $vH = vG$  for any convex  $l$ -subgroup  $H \neq \{0\}$  of  $G$ .  $G$  is said to be  $v$ -homogeneous  $l$ -group of  $\alpha$  type if  $vG = \alpha$ . An  $l$ -group  $G$  is said to be continuous, if for any  $0 < x \in G$  we have  $x = x_1 + x_2$  and  $x_1 \wedge x_2 = 0$ , where  $x_1 \neq 0$ ,  $x_2 \neq 0$ . By Theorem 3. 7 of [21] it

is easy to verify the following lemma, the proof is left to the reader.

**LEMMA 4. 1.** Any complete  $l$ -group is  $l$ -isomorphic to an ideal subdirect product of complete  $v$ -homogeneous  $l$ -groups.

By using 4. 3 of [21] it is easy to verify that if an  $l$ -group  $G$  is  $v$ -homogeneous and non-totally ordered, then  $v G \geq \aleph_0$ . It is well known that any non-zero complete totally ordered group is  $l$ -isomorphic to a real group  $R$  or an integer group  $Z$ . So from Lemma 4. 1 we obtain the structure of a complete  $l$ -group.

**THEOREM 4. 2.** Any complete  $l$ -group  $G$  is  $l$ -isomorphic to an ideal subdirect product of real groups, integer groups and complete  $v$ -homogeneous  $l$ -groups of  $\aleph_i$  type ( $i \geq 0$ ).

**LEMMA 4. 3.** (Proposition 2. 3 (1) of [22]) Let  $G$  be a  $v$ -homogeneous  $l$ -group of  $\aleph_i$  type and  $G \neq \{0\}$ . Then  $G$  has no basic element.

**LEMMA 4. 4.** (Lemma 2. 4 of [22]) A complete  $l$ -group  $G$  is continuous if and only if  $G$  has no basic element.

**COROLLARY 4. 5.** A complete  $v$ -homogeneous  $l$ -group of  $\aleph_i$  type is continuous.

Now we turn to an Archimedean  $l$ -group.

A subset  $D$  in a lattice  $L$  is called a  $d$ -set if there exists  $x \in L$  such that  $d_1 \wedge d_2 = x$  for any pair of distinct elements of  $D$  and  $d > x$  for each  $d \in D$ . We denote by  $w [a, b]$  the least cardinal  $\alpha$  such that  $|D| \leq \alpha$  for each  $d$ -set  $D$  of  $[a, b]$ .

**LEMMA 4. 6.** An  $l$ -group  $G$  is Archimedean if and only if  $G$  is  $l$ -isomorphic to a subdirect product of subgroups of reals and Archimedean  $v$ -homogeneous  $l$ -groups of  $\aleph_i$  type.

**Proof.** The sufficiency is clear. We need only to show the necessity.

Let  $G$  be an Archimedean  $l$ -group. Then  $G$  has the Dedekind completion  $G^\wedge$ . From Theorem 4. 2, without loss of generality, we have

$$\sum_{\delta \in \Delta} T_\delta \subseteq G^\wedge \subseteq \prod_{\delta \in \Delta} T_\delta, \tag{4. 1}$$

where  $T_\delta = R$  or  $Z$  or a continuous complete  $v$ -homogeneous  $l$ -group of  $\aleph_i$  type for each  $\delta \in \Delta$ . Let  $\rho_\delta$  be the projection map from  $G^\wedge$  onto  $T_\delta$ . Put  $\rho_\delta T_\delta = T'_\delta$ ,

$$\Delta_1 = \{\delta \in \Delta \mid T_\delta = R\}, \Delta_2 = \{\delta \in \Delta \mid T_\delta = Z\} \text{ and } \Delta_3 = \Delta \setminus (\Delta_1 \cup \Delta_2).$$

Thus, for  $\delta \in \Delta_1 \cup \Delta_2$   $T'_\delta$  is a subgroup of reals. For  $\delta \in \Delta_3$  we can show that  $T'_\delta$  is also  $v$ -homogeneous. In fact, for any  $a, b \in T'_\delta$  ( $a < b$ ), we denote by  $[a, b]^{r'}$  the interval in  $T'_\delta$  and by  $[a, b]^r$  the interval in  $T_\delta$ . We assume that  $w [a, b]^{r'} = \aleph_i$ .  $[a, b]^{r'} \subseteq [a, b]^r$  implies  $w [a, b]^{r'} \leq w [a, b]^r = \aleph_i$ . On the other hand, let  $\{c_j \mid j \in J, |J| = \aleph_i\}$  be a disjoint subest in  $[0, b - a]^{r'}$ . Since  $G$  is dense in  $G^\wedge$ ,  $T'_\delta$  is also dense in  $T_\delta$ . For each  $c_j$  ( $j \in J$ ), there exists  $0 < c'_j \in T'_\delta$  such that  $c'_j \leq c_j$ . Thus  $\{c'_j \mid j \in J\}$  is also a disjoint subset in  $[0, b - a]^{r'}$ . So  $w [a, b]^{r'} = w [0, b - a]^{r'} \geq \aleph_i$ . Therefore  $w [a, b]^{r'} = \aleph_i$  for any  $a, b \in T'_\delta$ , and so  $T'_\delta$  is  $w$ -homogeneous. From 3. 6 in [21]  $T'_\delta$  is  $v$ -homogeneous. Since  $T_\delta$  is complete,  $T'_\delta$  is Archimedean. From (4. 1) we have

$$G \subseteq \prod_{\delta \in \Delta} T'_\delta,$$

where each  $T'_\delta$  is a subgroup of reals or an Archimedean  $v$ -homogeneous  $l$ -group of  $\aleph_i$  type for  $\delta \in \Delta$ .

Suppose that  $G$  is a subdirect product of subgroups of reals and  $v$ -homogeneous  $l$ -groups of  $\aleph_i$  type,  $G \subseteq \prod_{\delta \in \Delta} T_\delta$ . Let  $\Delta_1 = \{\delta \in \Delta \mid T_\delta \text{ is a subgroup of reals}\}$ . If  $\sum_{\delta \in \Delta_1} T_\delta \subseteq G$ ,  $G$  is said to be a semicomplete subdirect product of subgroups of reals and  $v$ -homogeneous  $l$ -groups of  $\aleph_i$  type, in symbols  $\sum_{\delta \in \Delta_1 \subseteq \Delta} T_\delta \subseteq G \subseteq \prod_{\delta \in \Delta} T_\delta$ .

**THEOREM 4. 7.** An  $l$ -group  $G$  is Archimedean if and only if  $G$  is  $l$ -isomorphic to a semicomplete subdirect product of subgroups of reals and Archimedean  $v$ -homogeneous  $l$ -groups of  $\mathfrak{H}$ , type.

**Proof.** We need only to show the necessity. By Lemma 4. 6, without loss of generality, we have

$$G \subseteq \prod_{\delta \in \Delta} T_{\delta}' ,$$

where each  $T_{\delta}'$  is a subgroup of reals or an Archimedean  $v$ -homogeneous  $l$ -group of  $\mathfrak{H}$ , type. Put  $\Delta_1 = \{ \delta \in \Delta \mid T_{\delta}' \text{ is a subgroup of reals} \}$ . For each  $\delta \in \Delta_1$  and any  $0 < t_{\delta} \in T_{\delta}'$  there exists  $0 < x \in G$  such that  $x_{\delta} = t_{\delta}$ . Let  $\bar{t}_{\delta} = (0, \dots, 0, t_{\delta}, 0, \dots, 0)$  be the element with only one non-zero component  $t_{\delta}$ . Since  $\bar{t}_{\delta} \in G$  (see the formula (4. 1)) and  $G$  is dense in  $G$ , there exists  $\bar{t}'_{\delta} = (0, \dots, 0, t'_{\delta}, 0, \dots, 0) \in G$  such that  $t'_{\delta} \leq t_{\delta}$ . Because  $T_{\delta}'$  is a subgroup of reals, there exists some  $n \in \mathbb{N}$  such that  $t_{\delta} < nt'_{\delta}$ . Then  $x \wedge n \bar{t}'_{\delta} = \bar{t}'_{\delta} \in G$ . Hence  $T_{\delta}' \cong \bar{T}_{\delta} = \{ \bar{t}'_{\delta} \mid t_{\delta} \in T_{\delta}' \} \subseteq G$  for each  $\delta \in \Delta_1$ .

Therefore

$$\sum_{\delta \in \Delta_1} T_{\delta}' \subseteq G \subseteq \prod_{\delta \in \Delta} T_{\delta}' .$$

**5. THE RADICAL CLASSES GENERATED BY  $Z$**

For a family  $X$  of  $l$ -groups we denote by  $\mathcal{R}_{1'2i_3 \dots i_k}(X)$  the intersection of all  $1'2i_3 \dots i_k$ -classes containing  $X$  where  $i_3, \dots, i_k \in \{3, 3', 4, 4', 5, 6, 7\}$ . It is the smallest  $1'2i_3 \dots i_k$ -class containing  $X$  and said to be the  $1'2i_3 \dots i_k$ -class generated by  $X$ . The  $1'2i_3 \dots i_k$ -class generated by a single  $l$ -group  $G$  is denoted by  $\mathcal{R}_{1'2i_3 \dots i_k G}$ . It is well known that  $\mathcal{R}_{1'4Z} = \mathcal{A}$ , the variety of all abelian  $l$ -groups. In this section we will determine some radical classes generated by the integer group  $Z$ .

We recall that an element  $g > 0$  in an  $l$ -group  $G$  is singular if  $g = g_1 + g_2$  with  $g_1, g_2 > 0$  only when  $g_1 \wedge g_2 = 0$ . A negative element  $g$  is called a negative singular element if  $-g$  is a singular element.  $\mathcal{S}(G)$  will be denoted the set of all convex  $l$ -subgroups of an  $l$ -group  $G$ .

**LEMMA 5. 1.** An  $l$ -group  $G$  is a direct sum of  $Z$  if and only if  $G$  is a complete  $l$ -group which has no continuous convex  $l$ -subgroup and each element of  $G$  is a sum of singular elements and negative singular elements.

**Proof.** Let  $G = \sum_{\alpha \in A} Z_{\alpha}$ ,  $Z_{\alpha} = Z$  for all  $\alpha \in A$ . By Theorem 4. 2  $G$  is complete. Since  $Z$  is not continuous and every integer is a sum of singular elements 1 and negative singular elements  $-1$ ,  $G$  has no continuous convex  $l$ -subgroup and each element of  $G$  is a sum of singular element and negative singular elements. Conversely, if  $G$  is a complete  $l$ -group which has no continuous convex  $l$ -subgroup and each element of  $G$  is a sum of singular elements and negative singular elements. Since a complete  $v$ -homogeneous  $l$ -group of  $\mathfrak{H}$ , type is continuous and the real group  $R$  has no singular element, it follows from Theorem 4. 2 that  $G \subseteq \prod_{\alpha \in A} Z_{\alpha}$  with  $Z_{\alpha} = Z$  for all  $\alpha \in A$ . But each element of  $G$  is a sum of singular elements and negative singular elements, so  $G = \sum_{\alpha \in A} Z_{\alpha}$ .

**THEOREM 5. 2.**  $\mathcal{R}_{1'2Z} = \{ \sum_{\alpha \in A} Z_{\alpha} \mid Z_{\alpha} = Z \text{ for all } \alpha \in A \}$ .

**Proof.** First we prove that the set  $\mathcal{R}$  of all direct sums of  $Z$  is a  $1'2$ -class. It is clear that  $\mathcal{R}$  is closed under taking convex  $l$ -subgroups, because any convex  $l$ -subgroup of a direct sum of  $Z$  is still a direct sum of  $Z$ . Suppose that  $G_{\lambda} \in \mathcal{S}(G)$  and  $G_{\lambda} = \sum_{\alpha \in \Lambda_{\lambda}} Z_{\alpha}$  ( $Z_{\alpha} = Z$ ) for  $\lambda \in \Lambda$ . It is well known that  $\mathcal{S}$  of all complete  $l$ -groups is a radical class [13], that is  $\mathcal{S}$  is

closed under taking joins of convex  $l$ -subgroups. So  $\bigvee_{\lambda \in A}^{(G)} G_\lambda$  is complete.  $\bigvee_{\lambda \in A}^{(G)} G_\lambda$  has no continuous convex  $l$ -subgroup. In fact, if  $H$  is a convex  $l$ -subgroup of  $\bigvee_{\lambda \in A}^{(G)} G_\lambda$ . Since  $\mathcal{C}(G)$  is a Brouweian lattice,

$$H = H \cap \left( \bigvee_{\lambda \in A}^{(G)} G_\lambda \right) = \bigvee_{\lambda \in A}^{(G)} (H \cap G_\lambda).$$

Each  $H \cap G_\lambda$  is a convex  $l$ -subgroup of  $G_\lambda$ , so  $H \cap G_\lambda = \sum_{\alpha'_i \in A'_i \subseteq A_\lambda} Z_{\alpha'_i} (Z_{\alpha'_i} = Z)$ . Hence for each  $\lambda \in A$ , if  $0 < z_{\alpha'_i} \in Z_{\alpha'_i} \subseteq H$  ( $\alpha'_i \in A'_i$ ), then  $z_{\alpha'_i}$  cannot be expressed to  $z_{\alpha'_i} = x_1 + x_2$  such that  $x_1 \wedge x_2 = 0$  and  $x_1 \neq 0, x_2 \neq 0$ . So  $H$  is not continuous. Let  $x \in \bigvee_{\lambda \in A}^{(G)} G_\lambda$ . Then  $x = x_1 + \dots + x_n$  with  $x_i \in G_{\lambda_i}$ . Since each  $x_i$  is a sum of singular elements and negative singular elements,  $x$  is a sum of singular elements and negative singular elements. Therefore  $\bigvee_{\lambda \in A}^{(G)} G_\lambda$  is also a direct sum of  $Z$  by Lemma 5. 1.

Now suppose that  $\mathcal{U}$  is a 1'2-class containing  $Z$ . Let  $\sum_{\alpha \in A} Z_\alpha (Z_\alpha = Z)$  be a direct sum of  $Z$ . Since  $\mathcal{U}$  is closed under taking joins of convex  $l$ -subgroups and

$$\bigvee_{\alpha \in A}^{(\prod_{\alpha \in A} Z_\alpha)} Z_\alpha = \sum_{\alpha \in A} Z_\alpha$$

by Corollary 1 of Theorem 1. 5 in [15],  $\sum_{\alpha \in A} Z_\alpha \in \mathcal{U}$ . This shows that  $\mathcal{R}$  is the smallest 1'2-class containing  $Z$ .

**LEMMA 5. 3.** An  $l$ -group  $G$  is an ideal subdirect product of  $Z$  if and only if  $G$  is a complete  $l$ -group which has no continuous convex  $l$ -subgroup and each convex  $l$ -subgroup of  $G$  has a singular element.

**Proof.** The necessity is clear. Suppose that  $G$  is a complete  $l$ -group which has no continuous convex  $l$ -subgroup and each convex  $l$ -subgroup of  $G$  has a singular element. By Theorem 4. 2 we have

$$G \subseteq \prod_{\lambda \in A}^* G_\lambda$$

where each  $G_\lambda$  is  $Z$  or  $R$  or a complete  $v$ -homogeneous  $l$ -group of  $\mathfrak{H}_1$  type. Since a complete  $v$ -homogeneous  $l$ -group of  $\mathfrak{H}_1$  type is continuous and  $R$  has no singular element, so

$$G \subseteq \prod_{\lambda \in A}^* Z_\lambda$$

where  $Z_\lambda = Z$  for each  $\lambda \in A$ .

**THEOREM 5. 4.**  $\mathcal{R}_{1'23'Z} = \{G \mid G \subseteq \prod_{\alpha \in A}^* Z_\alpha, Z_\alpha = Z \text{ for all } \alpha \in A\}$ .

**Proof.** First we prove that the set  $\mathcal{R}$  of all ideal subdirect products of  $Z$  is a 1'23'-class.  $\mathcal{R}$  is closed under taking convex  $l$ -subgroups, because any convex  $l$ -subgroup of an ideal subdirect product of  $Z$  is still an ideal subdirect product of  $Z$ . Suppose that  $G$  is an  $l$ -group and  $G_\lambda \in \mathcal{C}(G)$ ,

$$G_\lambda \subseteq \prod_{\alpha_i \in A_i}^* Z_{\alpha_i} (Z_{\alpha_i} = Z)$$

for  $\lambda \in A$ . Similarly to the proof of Theorem 5. 2 we see that  $\bigvee_{\lambda \in A}^{(G)} G_\lambda$  is complete and has no continuous convex  $l$ -subgroup. Let  $H$  be a convex  $l$ -subgroup of  $\bigvee_{\lambda \in A}^{(G)} G_\lambda$ , then

$$H = \bigvee_{\lambda \in A}^{(G)} (H \cap G_\lambda).$$

For each  $\lambda \in A$ ,  $H \cap G_\lambda$  is a convex  $l$ -subgroup of  $G_\lambda$ , so  $H \cap G_\lambda \subseteq \prod_{\alpha_i \in A_i}^* Z_{\alpha_i} (Z_{\alpha_i} = Z)$ . Hence  $H$  has a singular element. It follows from Lemma 5. 3 that  $\bigvee_{\lambda \in A}^{(G)} G_\lambda \in \mathcal{R}$ .

Now suppose that  $\mathcal{U}$  is a 1'23'-class containing  $Z$ . Since a convex  $l$ -subgroup of direct product of  $Z$  is an ideal subdirect product of  $Z$ , so  $\mathcal{U} \supseteq \mathcal{R}$  and  $\mathcal{R}$  is the smallest 1'23'-class containing  $Z$ .

LEMMA 5. 5. An  $l$ -group  $G$  is a completely subdirect product of  $Z$  if and only if  $G$  is an Archimedean  $l$ -group which has no continuous convex  $l$ -subgroup and each convex  $l$ -subgroup of  $G$  has a singular element.

Proof. Necessity. Let  $\sum_{\alpha \in A} Z_\alpha \subseteq G \subseteq \prod_{\alpha \in A} Z_\alpha$  ( $Z_\alpha = Z$ ). By Theorem 4. 7  $G$  is Archimedean. It is clear that  $G$  has no continuous convex  $l$ -subgroup. Each convex  $l$ -subgroup  $H$  of  $G$  contains at least a  $Z_\alpha$ , so  $H$  has a singular element.

Sufficiency. Suppose that  $G$  is an Archimedean  $l$ -group which has no continuous convex  $l$ -subgroup and each convex  $l$ -subgroup of  $G$  has a singular element. By Theorem 4. 7 we have

$$\sum_{\lambda \in A} G_\lambda \subseteq G \subseteq \prod_{\lambda \in A} G_\lambda$$

where each  $G_\lambda$  is  $Z$  or  $R$ . But each  $G_\lambda$  is a convex  $l$ -subgroup of  $G$  and  $R$  has no singular element, so  $\sum_{\lambda \in A} Z_\lambda \subseteq G \subseteq \prod_{\lambda \in A} Z_\lambda$  ( $Z_\lambda = Z$ ).

THEOREM 5. 6.  $\mathcal{R}_{1'23Z} = \{G \mid \sum_{\alpha \in A} Z_\alpha \subseteq G \subseteq \prod_{\alpha \in A} Z_\alpha, Z_\alpha = Z \text{ for all } \alpha \in A\}$ .

Proof. First we prove that the set  $\mathcal{R}$  of all complete subdirect products of  $Z$  is a  $1'23$ -class.  $\mathcal{R}$  is closed under taking convex  $l$ -subgroups, because any convex  $l$ -subgroup of a completely subdirect product of  $Z$  is still a completely subdirect product of  $Z$ . Suppose that  $G$  is an  $l$ -group and  $G_\lambda \in \mathcal{C}(G)$ ,  $G_\lambda \in \mathcal{R}$  ( $\lambda \in \Lambda$ ). Since  $\mathcal{A}_1$ , the set of all Archimedean  $l$ -groups, is a quasi-torsion class [14] and is closed under taking joins of convex  $l$ -subgroups. So  $\bigvee_{\lambda \in \Lambda} {}^{(G)}G_\lambda$  is Archimedean. Similarly to the proof of Theorem 5. 2 and Theorem 5. 4 we see that  $\bigvee_{\lambda \in \Lambda} {}^{(G)}G_\lambda$  has no continuous convex  $l$ -subgroup and each convex  $l$ -subgroup of  $G$  has a singular element. It follows from Lemma 5. 5 that  $\bigvee_{\lambda \in \Lambda} {}^{(G)}G_\lambda \in \mathcal{R}$ . It is obvious that  $\mathcal{R}$  is the smallest  $1'23$ -class containing  $Z$ .

The following proposition is a corollary of Theorem 2. 7.

PROPOSITION 5. 7. Let  $G$  be an  $l$ -group, then we have the following relationship between the radical classes generated by  $G$ :

$$\begin{array}{cccccccc} & & & & & \mathcal{R}_{1'1'40} & & \\ & & & & & \cup & & \\ & & & & & \mathcal{R}_{1'20} & & \\ & & & & & \cup & & \\ \mathcal{R}_{1'1'40} & \supseteq & \mathcal{R}_{1'1'60} & \supseteq & \mathcal{R}_{1'1'30} & \supseteq & \mathcal{R}_{1'1'2'0} & \supseteq & \mathcal{R}_{1'20} & \subseteq & \mathcal{R}_{1'1'2'0} & \subseteq & \mathcal{R}_{1'1'40} & \subseteq & \mathcal{R}_{1'1'40} \\ & & \cap & & \cap & & \cap & & \cap & & \cap & & \cap & & \cap \\ \mathcal{R}_{1'1'2560} & \supseteq & \mathcal{R}_{1'1'2560} & \supseteq & \mathcal{R}_{1'1'2560} & \supseteq & \mathcal{R}_{1'1'2560} & \supseteq & \mathcal{R}_{1'1'2560} & \subseteq & \mathcal{R}_{1'1'2560} & \subseteq & \mathcal{R}_{1'1'2560} & \subseteq & \mathcal{R}_{1'1'2560} \\ & & \cap & & \cap & & \cap & & \cap & & \cap & & \cap & & \cap \\ \mathcal{R}_{1'1'2570} & = & \mathcal{R}_{1'1'2570} & = & \mathcal{R}_{1'1'2570} & = & \mathcal{R}_{1'1'2570} & = & \mathcal{R}_{1'1'27} & & & & & & & \end{array}$$

Let  $\mathcal{R}$  be a radical class. In [18] M. Darnel defined the order closure  $\mathcal{R}^c$  of  $\mathcal{R}$  with  $\mathcal{R}^c(G) = \overline{\mathcal{R}(G)}_o$  for any  $l$ -group  $G$ . It follows from Lemma 2. 2 and Proposition 5. 7 that

$$\mathcal{R}_{1'26Z} = \mathcal{R}_{1'2Z}^c = \mathcal{R}_{1'2'Z}^c = \mathcal{R}_{1'23Z}^c. \tag{5. 1}$$

From theorem 5. 2, Theorem 5. 4, Theorem 5. 6 and the formula (5. 1) we get

- THEOREM 5. 8. ( I )  $\mathcal{R}_{1'26Z} = \{G \mid G \text{ is an order closure of a convex } l\text{-subgroup } \sum_{\alpha \in A} Z_\alpha$  ( $Z_\alpha = Z$ ) of an  $l$ -group  $H\}$ .
- ( II )  $\mathcal{R}_{1'26Z} = \{G \mid G \text{ is an order closure of a convex } l\text{-subgroup } K \text{ of an } l\text{-group } H \text{ where } K \subseteq \prod_{\alpha \in A} Z_\alpha$  ( $Z_\alpha = Z$ )}.
- ( III )  $\mathcal{R}_{1'26Z} = \{G \mid G \text{ is an order closure of a convex } l\text{-subgroup } K \text{ of an } l\text{-group } H \text{ where } \sum_{\alpha \in A} Z_\alpha \subseteq K \subseteq \prod_{\alpha \in A} Z_\alpha$  ( $Z_\alpha = Z$ )}.

From Lemma 2. 4, Theorem 5. 2, Theorem 5. 4, Theorem 5. 6 and Proposition 5. 7 we have

**THEOREM 5. 9.** ( I )  $\mathcal{R}_{1'27Z} = \{G \mid G \text{ is a double polar of a convex } l\text{-subgroup } \sum_{\alpha \in A} Z_\alpha \text{ (} Z_\alpha = Z \text{) of an } l\text{-group } H\}$ .

( II )  $\mathcal{R}_{1'27Z} = \mathcal{R}_{1'23'7Z} = \{G \mid G \text{ is a double polar of a convex } l\text{-subgroup } K \text{ of an } l\text{-group } H \text{ where } K \subseteq \prod_{\alpha \in A} Z_\alpha \text{ (} Z_\alpha = Z \text{)}\}$ .

( III )  $\mathcal{R}_{1'27Z} = \mathcal{R}_{1'237Z} = \{G \mid G \text{ is a double polar of a convex } l\text{-subgroup } K \text{ of an } l\text{-group } H \text{ where } \sum_{\alpha \in A} Z_\alpha \subseteq K \subseteq \prod_{\alpha \in A} Z_\alpha \text{ (} Z_\alpha = Z \text{)}\}$ .

**LEMMA 5. 10.** Let  $\mathcal{R}$  be a radical class, then  $\mathcal{R}^{\perp\perp} = \{G \mid \text{for each convex } l\text{-subgroup } C \text{ of } G \mathcal{R}(C) \neq 0\}$ .

**Proof.**  $\mathcal{R}^\perp(G)$  is the largest convex  $l$ -subgroup  $C$  of  $G$  such that  $\mathcal{R}(C) = 0$ . So  $\mathcal{R}^\perp(G) = 0$  if and only if for each convex  $l$ -subgroup  $C$  of  $G$   $\mathcal{R}(C) \neq 0$ . Since  $\mathcal{R}^\perp(G) = \mathcal{R}(G)^\perp$ ,  $G \in \mathcal{R}^{\perp\perp}$  if and only if  $\mathcal{R}^\perp(G) = 0$ , if and only if for each convex  $l$ -subgroup  $C$  of  $G$   $\mathcal{R}(C) \neq 0$ .

Let  $\mathcal{R}$  be a radical class. It is clear that  $\mathcal{R}^{\perp\perp}$  is the smallest polar radical class containing  $\mathcal{R}$ . From Lemma 2. 4 and Lemma 5. 10 we get

**THEOREM 5. 11.**  $\mathcal{R}_{1'27Z} = \mathcal{R}_{1'2Z}^{\perp\perp} = \{G \mid \text{each convex } l\text{-subgroup of } G \text{ contains a convex } l\text{-subgroup } \sum_{\alpha \in A} Z_\alpha \text{ (} Z_\alpha = Z \text{)}\}$ .

**6. THE RADICAL CLASSES GENERATED BY R**

In this section we will determine some radical classes generated by the real group R.

**LEMMA 6. 1.** An  $l$ -group  $G$  is a direct sum of R if and only if  $G$  is a complete  $l$ -group which has no continuous convex  $l$ -subgroup and for each principal convex  $l$ -subgroup  $C$  of  $G$   $vC$  is finite and  $|C| > \aleph_0$ .

**Proof.** Let  $G = \sum_{\alpha \in A} R_\alpha$  ( $R_\alpha = R$ ). By Theorem 4. 2  $G$  is complete. Since R is not continuous and R is a totally ordered group,  $G$  has no continuous convex  $l$ -subgroup and  $|K| > \aleph_0$  for each convex  $l$ -subgroup  $K$  of  $G$ . Since each element of  $G$  has only finitely many non-zero components,  $vC$  is finite for each principal convex  $l$ -subgroup  $C$  of  $G$ .

Conversely, suppose that  $G$  satisfies the conditions of Lemma.6. 1. Since a complete  $v$ -homogeneous  $l$ -group of  $\aleph_i$  type is continuous and  $|Z| = \aleph_0$ ,  $G \subseteq \prod_{\alpha \in A} R_\alpha$  ( $R_\alpha = R$ ) by Theorem 4. 2. The fact that  $vC$  is finite for each principal convex  $l$ -subgroup  $C$  of  $G$  implies that each element of  $G$  has only finitely many non-zero components. Therefore  $G = \sum_{\alpha \in A} R_\alpha$  ( $R_\alpha = R$ ).

**THEOREM 6. 2.**  $\mathcal{R}_{1'2R} = \{ \sum_{\alpha \in A} R_\alpha \mid R_\alpha = R \text{ for all } \alpha \in A \}$ .

**Proof.** We can prove that the set  $\mathcal{R}$  of all direct sums of R is a 1'2-class. It is clear that  $\mathcal{R}$  is closed under taking convex  $l$ -subgroups. Suppose that  $G$  is an  $l$ -group and  $G_\lambda \in \mathcal{R}(G)$ ,  $G_\lambda = \sum_{\alpha \in A_\lambda} R_\alpha$  ( $R_\alpha = R$ ) for  $\lambda \in \Lambda$ . Similarly to the proof of Theorem 5. 2 we can show that  $\bigvee_{\lambda \in \Lambda}^{(0)} G_\lambda$  is complete and has no continuous convex  $l$ -subgroup.

Now we prove that  $vC$  is finite for each principal convex  $l$ -subgroup  $C$  of  $\bigvee_{\lambda \in \Lambda}^{(0)} G_\lambda$ . Let  $0 < x \in \bigvee_{\lambda \in \Lambda}^{(0)} G_\lambda$ . Then

$$x = x_1 + \dots + x_n \leq x_1^+ + \dots + x_n^+ ,$$

where  $x_\lambda \in G_\lambda$  ( $1 \leq i \leq n$ ). Let  $G_0$  be the convex  $l$ -subgroup generated by  $x$  in  $\bigvee_{\lambda \in \Lambda}^{(0)} G_\lambda$ . Sup-

pose that  $\{x_\alpha | \alpha \in A\}$  is a disjoint subset of  $G_0$ . We assume  $x_\alpha \leq x$  for each  $\alpha \in A$  (otherwise let  $\bar{x}_\alpha = x_\alpha \wedge x$ ). Put  $x'_i = x_\alpha \wedge x_{\lambda_i}^+$ ,  $i=1, \dots, n$ . For each  $\alpha \in A$  there at least exists  $x'_\alpha \neq 0$ . Because if all  $x'_\alpha = 0$  ( $i=1, \dots, n$ ), then

$$0 < x_\alpha = x_\alpha \wedge x \leq x_\alpha \wedge (x_{\lambda_1}^+ + \dots + x_{\lambda_n}^+) \leq x_\alpha \wedge x_{\lambda_1}^+ + \dots + x_\alpha \wedge x_{\lambda_n}^+ = 0,$$

a contradiction. It is clear that

$$x'_\alpha \wedge x'_{\alpha'} = x_\alpha \wedge x_{\alpha'} \wedge x_{\lambda_i}^+ = 0 (\alpha \neq \alpha'),$$

and so  $\{x'_\alpha | \alpha \in A\}$  is a disjoint subset of  $G_\lambda(x_{\lambda_i}^+)$  for  $i=1, \dots, n$ . Since  $v G_\lambda(x_{\lambda_i}^+)$  is finite for  $i=1, \dots, n$ ,  $|A|$  must be finite. Combining the above we see that  $\bigvee_{\lambda \in A}^{(G)} G_\lambda = \sum_{\alpha \in A} H_\alpha$  ( $H_\alpha = \mathbb{Z}$  or  $\mathbb{R}$ ) by Theorem 4. 2. Since any convex  $l$ -subgroup  $K$  of  $\sum_{\alpha \in A} H_\alpha$  is also a join of direct sums of  $\mathbb{R}$  and  $|K| > \aleph_0$ ,  $\sum_{\alpha \in A} H_\alpha$  cannot contain  $\mathbb{Z}$  as a convex  $l$ -subgroup. Hence  $\bigvee_{\lambda \in A}^{(G)} G_\lambda = \sum_{\alpha \in A} R_\alpha$  ( $R_\alpha = \mathbb{R}$ ) by Lemma 6. 1.

Similarly to the proof of Theorem 5. 2 we can show that  $\mathcal{R}$  is the smallest 1' 2-class containing  $\mathbb{R}$ .

**LEMMA 6. 3.** An  $l$ -group  $G$  is an ideal subdirect product of  $\mathbb{R}$  if and only if  $G$  is a complete  $l$ -group which has no continuous convex  $l$ -subgroup and  $|K| > \aleph_0$  for each convex  $l$ -subgroup  $K$  of  $G$ .

The proof of this lemma is obvious by Theorem 4. 2.

**THEOREM 6. 4.**  $\mathcal{R}_{1'23\mathbb{R}} = \{G | G \subseteq \prod_{\alpha \in A} R_\alpha, R_\alpha = \mathbb{R} \text{ for all } \alpha \in A\}$ .

The proof of this theorem is similar to those of Theorem 5. 4 and Theorem 6. 2.

**LEMMA 6. 5.** An  $l$ -group  $G$  is a completely subdirect product of  $\mathbb{R}$  if and only if  $G$  is an Archimedean  $l$ -group which has no continuous convex  $l$ -subgroup and  $|K| > \aleph_0$  for each convex  $l$ -subgroup  $K$  of  $G$ .

The proof of this lemma is obvious by Theorem 4. 7.

**THEOREM 6. 6.**  $\mathcal{R}_{1'23\mathbb{R}} = \{G | \sum_{\alpha \in A} R_\alpha \subseteq G \subseteq \prod_{\alpha \in A} R_\alpha, R_\alpha = \mathbb{R} \text{ for all } \alpha \in A\}$ .

The proof of this theorem is similar to those of Theorem 5. 6 and Theorem 6. 2.

Similarly to Theorem 5. 8 we have

**THEOREM 6. 7.** ( I )  $\mathcal{R}_{1'26\mathbb{R}} = \{G | G \text{ is an order closure of a convex } l\text{-subgroup } \sum_{\alpha \in A} R_\alpha$  ( $R_\alpha = \mathbb{R}$ ) of an  $l$ -group  $H\}$ .

( II )  $\mathcal{R}_{1'26\mathbb{R}} = \{G | G \text{ is an closure of a convex } l\text{-subgroup } K \text{ of an } l\text{-group } H \text{ where } K \subseteq \prod_{\alpha \in A} R_\alpha$  ( $R_\alpha = \mathbb{R}$ )\}.

( III )  $\mathcal{R}_{1'26\mathbb{R}} = \{G | G \text{ is an order closure of a convex } l\text{-subgroup } K \text{ of an } l\text{-group } H$  where  $\sum_{\alpha \in A} R_\alpha \subseteq K \subseteq \prod_{\alpha \in A} R_\alpha$  ( $R_\alpha = \mathbb{R}$ )\}.

Similar to Theorem 5. 9 we have

**THEOREM 6. 8.** ( I )  $\mathcal{R}_{1'27\mathbb{R}} = \{G | G \text{ is a double polar of a convex } l\text{-subgroup } \sum_{\alpha \in A} R_\alpha$  ( $R_\alpha = \mathbb{R}$ ) of an  $l$ -group  $H\}$ .

( II )  $\mathcal{R}_{1'27\mathbb{R}} = \mathcal{R}_{1'237\mathbb{R}} = \{G | G \text{ is a double polar of a convex } l\text{-subgroup } K \text{ of an } l\text{-group } H \text{ where } K \subseteq \prod_{\alpha \in A} R_\alpha$  ( $R_\alpha = \mathbb{R}$ )\}.

( III )  $\mathcal{R}_{1'27\mathbb{R}} = \mathcal{R}_{1'237\mathbb{R}} = \{G | G \text{ is a double polar of a convex } l\text{-subgroup } K \text{ of an } l\text{-group } H \text{ where } \sum_{\alpha \in A} R_\alpha \subseteq K \subseteq \prod_{\alpha \in A} R_\alpha$  ( $R_\alpha = \mathbb{R}$ )\}.

Similarly to Theorem 5. 11 we have

**THEOREM 6.9.**  $\mathcal{R}_{l'2R}^{\perp\perp} = \mathcal{R}_{l'2R}^{\perp\perp} = \{G \mid \text{each convex } l\text{-subgroup of } G \text{ contains a convex } l\text{-subgroup } \sum_{a \in A} R_a \text{ (} R_a = R \text{)}\}$ .

### 7. AN EXAMPLE

We consider the total ordered group  $Z \bar{\times} Z$ .  $Z_0 = \{ (0, z) \mid z \in Z \} \cong Z$  is an  $l$ -ideal of  $Z \bar{\times} Z$ . It is clear that  $Z_0^{\perp\perp} = Z \bar{\times} Z$  and  $Z \bar{\times} Z / Z_0 \cong Z_0$ . So  $Z \bar{\times} Z \in \mathcal{R}_{l'2Z}$  and  $Z \bar{\times} Z \in \mathcal{R}_{l'25Z}$ , but  $Z \bar{\times} Z \notin \mathcal{R}_{l'2Z}$ . Hence  $\mathcal{R}_{l'2Z} \neq \mathcal{R}_{l'25Z}$ .  $\mathcal{R}_{l'25Z} = \mathcal{R}_{l'2Z}$ .

Similarly,  $R \bar{\times} R \in \mathcal{R}_{l'25R}$  and  $R \bar{\times} R \notin \mathcal{R}_{l'2R}$ . Hence  $\mathcal{R}_{l'2R} \neq \mathcal{R}_{l'25R}$ ,  $\mathcal{R}_{l'25R} = \mathcal{R}_{l'2R}$ .

Note. Since  $Z$  and  $R$  have no proper convex  $l$ -subgroup,  $\mathcal{R}_{l'2Z}$  and  $\mathcal{R}_{l'2R}$  are closed under  $l$ -homomorphisms. Therefore  $\mathcal{R}_{l'24'Z} = \mathcal{R}_{l'24Z} = \mathcal{R}_{l'2Z}$  and  $\mathcal{R}_{l'24'R} = \mathcal{R}_{l'24R} = \mathcal{R}_{l'2R}$ .
