

# Combinatorial Dyson-Schwinger equations and systems I

Loïc Foissy

Bertinoro  
September 2013

In QFT, one studies the behaviour of particles in a quantum fields.

- Several types of particles: electrons, photons, bosons, etc.
- Several types of interactions: an electron can capture/eject a photon, etc.

One wants to predict certain physical constants: mass or charge of the electron, etc.

- Develop the constant in a formal series, indexed by certain combinatorial objects: the Feynman graphs.
- Attach to any Feynman graph a real/complex number: Feynman rules and Renormalization.

- The expansion as a formal series gives formal sums of Feynman graphs: the propagators (vertex functions, two-points functions).
- These formal sums are characterized by a set of equations: the Dyson-Schwinger equations.
- In order to be "physically meaningful", these functions should be compatible with the extraction/contraction Hopf algebra structure on Feynman graphs. This imposes strong constraints on the Dyson-Schwinger equations.
- Because of a 1-cocycle property, everything can be lifted and studied to the level of decorated rooted trees.

To a given QFT is attached a family of graphs.

## Feynman graphs

- 1 A finite number of possible half-edges.
- 2 A finite number of possible vertices.
- 3 A finite number of possible external half-edges (external structure).
- 4 The graph is connected and 1-PI.

To each external structure is associated a formal series in the Feynman graphs.

## In QED

1 Half-edges:  $\rightarrow$  (electron),  $\sim$  (photon).

2 Vertices:  $\sim \rightarrow$ .

3 External structures:  $\sim \textcircled{\times} \rightarrow$ ,  $\rightarrow \textcircled{\times} \rightarrow$ ,  $\sim \textcircled{\times} \sim$ .

## Examples in QED

## Other examples

- $\phi^3$ .
- Quantum Chromodynamics.

## Subgraphs and contraction

- 1 A subgraph of a Feynman graph  $\Gamma$  is a subset  $\gamma$  of the set of half-edges  $\Gamma$  such that  $\gamma$  and the vertices of  $\Gamma$  with all half edges in  $\gamma$  is itself a Feynman graph.
- 2 If  $\Gamma$  is a Feynman graph and  $\gamma_1, \dots, \gamma_k$  are disjoint subgraphs of  $\Gamma$ ,  $\Gamma/\gamma_1 \dots \gamma_k$  is the Feynman graph obtained by replacing  $\gamma_1, \dots, \gamma_k$  by vertices in  $\Gamma$ .

## Insertion

Let  $\Gamma_1$  and  $\Gamma_2$  be two Feynman graphs. According to the external structure of  $\Gamma_1$ , you can replace a vertex or an edge of  $\Gamma_2$  by  $\Gamma_1$  in order to obtain a new Feynman graph.

## Examples in QED

Let  $A$  and  $B$  be two vector spaces.

- The tensor product of  $A$  and  $B$  is a space  $A \otimes B$  with a bilinear product  $\otimes : A \times B \longrightarrow A \otimes B$  satisfying a universal property: if  $f : A \times B \longrightarrow C$  is bilinear, there exists a unique linear map  $F : A \otimes B \longrightarrow C$  such that  $F(a \otimes b) = f(a, b)$  for all  $(a, b) \in A \times B$ .
- If  $(e_i)_{i \in I}$  is a basis of  $A$  and  $(f_j)_{j \in J}$  is a basis of  $B$ , then  $(e_i \otimes f_j)_{i \in I, j \in J}$  is a basis  $A \otimes B$ .

- The tensor product of vector spaces is associative:  
 $(A \otimes B) \otimes C = A \otimes (B \otimes C)$ .
- We shall identify  $K \otimes A$ ,  $A \otimes K$  and  $A$  via the identification of  $1 \otimes a$ ,  $a \otimes 1$  and  $a$ .

If  $A$  is an associative algebra, its (bilinear) product becomes a linear map  $m : A \otimes A \longrightarrow A$ , sending  $a \otimes b$  on  $ab$ . The associativity is given by the following commuting square:

$$\begin{array}{ccc}
 A \otimes A \otimes A & \xrightarrow{m \otimes Id} & A \otimes A \\
 Id \otimes m \downarrow & & \downarrow m \\
 A \otimes A & \xrightarrow{m} & A
 \end{array}$$

If  $A$  is unitary, its unit  $1_A$  induces a linear map

$$\eta : \begin{cases} K & \longrightarrow A \\ \lambda & \longrightarrow \lambda 1_A. \end{cases}$$

The unit axiom becomes:

$$\begin{array}{ccccc} K \otimes A & \xrightarrow{\eta \otimes Id} & A \otimes A & \xleftarrow{Id \otimes \eta} & A \otimes K \\ & \searrow & \downarrow m & \swarrow & \\ & & A & & \end{array}$$

Dualizing these diagrams, we obtain the coalgebra axioms

## Coalgebra

A coalgebra is a vector space  $C$  with a map  $\Delta : C \rightarrow C \otimes C$  such that:

$$\begin{array}{ccc}
 C & \xrightarrow{\Delta} & C \otimes C \\
 \Delta \downarrow & & \downarrow Id \otimes \Delta \\
 C \otimes C & \xrightarrow{\Delta \otimes Id} & C \otimes C \otimes C
 \end{array}$$

## Coalgebra

- There exists a map  $\varepsilon : C \longrightarrow K$ , called the counit, such that:

$$\begin{array}{ccccc} K \otimes C & \xleftarrow{\varepsilon \otimes Id} & C \otimes C & \xrightarrow{Id \otimes \varepsilon} & C \otimes K \\ & \searrow & \uparrow \Delta & \swarrow & \\ & & C & & \end{array}$$

If  $A$  is an algebra, then  $A \otimes A$  is an algebra, with:

$$(a_1 \otimes b_1).(a_2 \otimes b_2) = (a_1.a_2) \otimes (b_1.b_2).$$

## Bialgebra and Hopf algebra

- A bialgebra is both an algebra and a coalgebra, such that the coproduct and the counit are algebra morphisms.
- A Hopf algebra is a bialgebra with a technical condition of existence of an antipode.

## Examples

- If  $G$  is a group,  $KG$  is a Hopf algebra, with  $\Delta(x) = x \otimes x$  for all  $x \in G$ .
- If  $\mathfrak{g}$  is a Lie algebra, its enveloping algebra is a Hopf algebra, with  $\Delta(x) = x \otimes 1 + 1 \otimes x$  for all  $x \in \mathfrak{g}$ .
- If  $H$  is a finite-dimensional Hopf algebra, then its dual is also a Hopf algebra.
- If  $H$  is a graded Hopf algebra, then its graded dual is also a Hopf algebra.

## Construction

Let  $H_{FG}$  be a free commutative algebra generated by the set of Feynman graphs. It is given a coproduct: for all Feynman graph  $\Gamma$ ,

$$\Delta(\Gamma) = \sum_{\gamma_1 \dots \gamma_k \subseteq \Gamma} \gamma_1 \dots \gamma_k \otimes \Gamma / \gamma_1 \dots \gamma_k.$$

The diagrammatic equation shows the coproduct of a loop graph with four external legs. The left side is  $\Delta(\text{loop graph})$ . The right side is the sum of three terms:  $\text{loop graph with one leg cut} \otimes 1$ ,  $1 \otimes \text{loop graph with one leg cut}$ , and  $\text{loop graph with a bubble cut} \otimes \text{loop graph with one leg cut}$ .

The Hopf algebra  $H_{FG}$  is graded by the number of loops:

$$|\Gamma| = \#E(\Gamma) - \#V(\Gamma) + 1.$$

Because of the 1-PI condition, it is connected, that is to say  $(H_{FG})_0 = K1_{H_{FG}}$ . What is its dual?

### Cartier-Quillen-Milnor-Moore theorem

Let  $H$  be a cocommutative, graded, connected Hopf algebra over a field of characteristic zero. Then it is the enveloping algebra of its primitive elements.

This theorem can be applied to the graded dual of  $H_{FG}$ .

### Primitive elements of $H_{FG}^*$

- Basis of primitive elements: for any Feynman graph  $\Gamma$ ,

$$f_{\Gamma}(\gamma_1 \dots \gamma_k) = \#Aut(\Gamma) \delta_{\gamma_1 \dots \gamma_k, \Gamma}.$$

- The Lie bracket is given by:

$$[f_{\Gamma_1}, f_{\Gamma_2}] = \sum_{\Gamma = \Gamma_1 \succ \Gamma_2} f_{\Gamma} - \sum_{\Gamma = \Gamma_2 \succ \Gamma_1} f_{\Gamma}.$$

We define:

$$f_{\Gamma_1} \circ f_{\Gamma_2} = \sum_{\Gamma = \Gamma_1 \times \Gamma_2} f_{\Gamma}.$$

The product  $\circ$  is not associative, but satisfies:

$$f_1 \circ (f_2 \circ f_3) - (f_1 \circ f_2) \circ f_3 = f_2 \circ (f_1 \circ f_3) - (f_2 \circ f_1) \circ f_3.$$

It is (left) prelie.

In the context of QFT, we shall consider some special infinite sums of Feynman graphs:

## Propagators in QED

$$\begin{aligned}
 \text{Diagram 1} &= \sum_{n \geq 1} x^n \left( \sum_{\gamma \in \text{Diagram 1}(n)} s_{\gamma} \gamma \right) \\
 \text{Diagram 2} &= - \sum_{n \geq 1} x^n \left( \sum_{\gamma \in \text{Diagram 2}(n)} s_{\gamma} \gamma \right)
 \end{aligned}$$

## Propagators in QED

$$\text{wavy line with a circle} = - \sum_{n \geq 1} x^n \left( \sum_{\gamma \in \text{wavy line with a circle}(n)} s_{\gamma} \gamma \right).$$

They live in the completion of  $H_{FG}$ .

## How to describe the propagators?

- For any primitive Feynman graph  $\gamma$ , one defines the insertion operator  $B_\gamma$  over  $H_{FG}$ . This operator associates to a graph  $G$  the sum (with symmetry coefficients) of the insertions of  $G$  into  $\gamma$ .
- The propagators then satisfy a system of equations involving the insertion operators, called systems of Dyson-Schwinger equations.

## Example

In QED :

$$B \left( \begin{array}{c} \text{---} \\ \text{---} \\ \text{---} \end{array} \right) = \frac{1}{2} \left( \begin{array}{c} \text{---} \\ \text{---} \\ \text{---} \end{array} \right) + \frac{1}{2} \left( \begin{array}{c} \text{---} \\ \text{---} \\ \text{---} \end{array} \right)$$

$$B \left( \begin{array}{c} \text{---} \\ \text{---} \\ \text{---} \end{array} \right) = \frac{1}{3} \left( \begin{array}{c} \text{---} \\ \text{---} \\ \text{---} \end{array} \right) + \frac{1}{3} \left( \begin{array}{c} \text{---} \\ \text{---} \\ \text{---} \end{array} \right) + \frac{1}{3} \left( \begin{array}{c} \text{---} \\ \text{---} \\ \text{---} \end{array} \right)$$

In QED:

$$\begin{array}{c} \text{wavy line with a shaded circle and two outgoing arrows} \end{array} = \sum_{\gamma} x^{|\gamma|} B_{\gamma} \left( \frac{\left( 1 + \begin{array}{c} \text{wavy line with a shaded circle and two outgoing arrows} \end{array} \right)^{1+2|\gamma|}}{\left( 1 + \begin{array}{c} \text{wavy line with a shaded circle} \end{array} \right)^{|\gamma|} \left( 1 + \begin{array}{c} \text{wavy line with a shaded circle and two outgoing arrows} \end{array} \right)^{2|\gamma|}} \right)$$

$$\begin{array}{c} \text{wavy line with a shaded circle} \end{array} = -xB \begin{array}{c} \text{wavy line with a shaded circle} \end{array} \left( \frac{\left( 1 + \begin{array}{c} \text{wavy line with a shaded circle and two outgoing arrows} \end{array} \right)^2}{\left( 1 + \begin{array}{c} \text{wavy line with a shaded circle and two outgoing arrows} \end{array} \right)^2} \right)$$

$$\begin{array}{c} \text{wavy line with a shaded circle and two outgoing arrows} \end{array} = -xB \begin{array}{c} \text{wavy line with a shaded circle and two outgoing arrows} \end{array} \left( \frac{\left( 1 + \begin{array}{c} \text{wavy line with a shaded circle and two outgoing arrows} \end{array} \right)^2}{\left( 1 + \begin{array}{c} \text{wavy line with a shaded circle} \end{array} \right) \left( 1 + \begin{array}{c} \text{wavy line with a shaded circle and two outgoing arrows} \end{array} \right)} \right)$$

## Other example (Bergbauer, Kreimer)

$$X = \sum_{\gamma \text{ primitive}} B_{\gamma} \left( (1 + X)^{|\gamma|+1} \right).$$

## Question

For a given system of Dyson-Schwinger equations  $(S)$ , is the subalgebra generated by the homogeneous components of  $(S)$  a Hopf subalgebra?

## Proposition

The operators  $B_\gamma$  satisfy: for all  $x \in H_{FG}$ ,

$$\Delta \circ B_\gamma(x) = B_\gamma(x) \otimes 1 + (Id \otimes B_\gamma) \circ \Delta(x).$$

This relation allows to lift any system of Dyson-Schwinger equation to the Hopf algebra of decorated rooted trees.

## Cartier-Quillen cohomology

let  $C$  be a coalgebra and let  $(B, \delta_G, \delta_D)$  be a  $C$ -bicomodule.

- $D_n = \mathcal{L}(B, C^{\otimes n})$ .
- For all  $l \in D_n$ :

$$b_n(L) = \sum_{i=1}^n (-1)^i (Id^{\otimes(i-1)} \otimes \Delta \otimes Id^{\otimes(n-i)}) \circ L \\ + (Id \otimes L) \circ \delta_G + (-1)^{n+1} (L \otimes Id) \circ \delta_D.$$

## A particular case

We take  $B = C$ ,  $\delta_G(b) = \Delta(b)$  and  $\delta_D(b) = b \otimes 1$ . A 1-cocycle of  $C$  is a linear map  $L : C \rightarrow C$ , such that for all  $b \in C$ :

$$(Id \otimes L) \circ \Delta(b) - \Delta \circ L(b) + b \otimes 1 = 0.$$

So  $B_\gamma$  is a 1-cocycle of  $H_{FG}$  for all primitive Feynman graph.

The Hopf algebra of rooted trees  $H_R$  (or Connes-Kreimer Hopf algebra) is the free commutative algebra generated by the set of rooted trees.

The set of rooted forests is a linear basis of  $H_R$ :

The coproduct is given by admissible cuts:

$$\Delta(t) = \sum_{c \text{ admissible cut}} P^c(t) \otimes R^c(t).$$

cut $c$										total
Admissible ?	yes	yes	yes	yes	no	yes	yes	no	yes	yes
$W^c(t)$										
$R^c(t)$					$\times$	$\cdot$		$\times$	$\times$	1
$P^c(t)$	1		$\cdot$	$\cdot$	$\times$			$\times$	$\times$	

$$\Delta(\text{rooted tree with one node}) = \text{rooted tree with one node} \otimes 1 + 1 \otimes \text{rooted tree with one node} + \text{rooted tree with one node} \otimes \text{rooted tree with one node} + \cdot \otimes \text{rooted tree with one node} + \cdot \otimes \text{rooted tree with one node} + \text{rooted tree with one node} \otimes \cdot + \text{rooted tree with one node} \otimes \cdot + \cdot \otimes \text{rooted tree with one node}.$$

The grafting operator of  $H_R$  is the map  $B : H_R \longrightarrow H_R$ , associating to a forest  $t_1 \dots t_n$  the tree obtained by grafting  $t_1, \dots, t_n$  on a common root. For example:

$$B(\bullet \bullet) = \begin{array}{c} \bullet \\ | \\ \vee \\ / \quad \backslash \\ \bullet \quad \bullet \end{array}.$$

## Proposition

For all  $x \in H_R$ :

$$\Delta \circ B(x) = B(x) \otimes 1 + (Id \otimes B) \circ \Delta(x).$$

So  $B$  is a 1-cocycle of  $H_R$ .

## Universal property

Let  $A$  be a commutative Hopf algebra and let  $L : A \longrightarrow A$  be a 1-cocycle of  $A$ . Then there exists a unique Hopf algebra morphism  $\phi : H_R \longrightarrow A$  with  $\phi \circ B = L \circ \phi$ .

This will be generalized to the case of several 1-cocycles with the help of decorated rooted trees.

- $H_R$  is graded by the number of vertices and  $B$  is homogeneous of degree 1.
- Let  $Y = B_\gamma(f(Y))$  be a Dyson-Schwinger equation in a suitable Hopf algebra of Feynman graphs  $H_{FG}$ , such that  $|\gamma| = 1$ .
- There exists a Hopf algebra morphism  $\phi : H_R \longrightarrow H_{FG}$ , such that  $\phi \circ B = B_\gamma \circ \phi$ . This morphism is homogeneous of degree 0.
- Let  $X$  be the solution of  $X = B(f(X))$ . Then  $\phi(X) = Y$  and for all  $n \geq 1$ ,  $\phi(X(n)) = Y(n)$ .
- Consequently, if the subalgebra generated by the  $X(n)$ 's is Hopf, so is the subalgebra generated by the  $Y(n)$ 's.

## Definition

Let  $f(h) \in K[[h]]$ .

- The combinatorial Dyson-Schwinger equations associated to  $f(h)$  is:

$$X = B(f(X)),$$

where  $X$  lives in the completion of  $H_R$ .

- This equation has a unique solution  $X = \sum X(n)$ , with:

$$\begin{cases} X(1) = p_0 \bullet, \\ X(n+1) = \sum_{k=1}^n \sum_{a_1 + \dots + a_k = n} p_k B(X(a_1) \dots X(a_k)), \end{cases}$$

where  $f(h) = p_0 + p_1 h + p_2 h^2 + \dots$

$$X(1) = p_0 \bullet,$$

$$X(2) = p_0 p_1 \downarrow,$$

$$X(3) = p_0 p_1^2 \downarrow + p_0^2 p_2 \vee,$$

$$X(4) = p_0 p_1^3 \downarrow + p_0^2 p_1 p_2 \downarrow + 2 p_0^2 p_1 p_2 \vee + p_0^3 p_3 \Downarrow.$$

## Examples

- If  $f(h) = 1 + h$ :

$$X = \bullet + \begin{array}{c} \bullet \\ | \\ \bullet \end{array} + \begin{array}{c} \bullet \\ | \\ \bullet \\ | \\ \bullet \end{array} + \begin{array}{c} \bullet \\ | \\ \bullet \\ | \\ \bullet \\ | \\ \bullet \end{array} + \begin{array}{c} \bullet \\ | \\ \bullet \\ | \\ \bullet \\ | \\ \bullet \\ | \\ \bullet \end{array} + \dots$$

- If  $f(h) = (1 - h)^{-1}$ :

$$X = \bullet + \begin{array}{c} \bullet \\ | \\ \bullet \end{array} + \begin{array}{c} \bullet \\ / \backslash \\ \bullet \quad \bullet \end{array} + \begin{array}{c} \bullet \\ | \\ \bullet \\ | \\ \bullet \end{array} + \begin{array}{c} \bullet \\ / \backslash \\ \bullet \quad \bullet \\ | \quad | \\ \bullet \quad \bullet \end{array} + 2 \begin{array}{c} \bullet \\ | \\ \bullet \\ | \\ \bullet \end{array} + \begin{array}{c} \bullet \\ / \backslash \\ \bullet \quad \bullet \\ | \quad | \\ \bullet \quad \bullet \\ | \quad | \\ \bullet \quad \bullet \end{array} + \begin{array}{c} \bullet \\ | \\ \bullet \\ | \\ \bullet \\ | \\ \bullet \end{array} + \begin{array}{c} \bullet \\ / \backslash \\ \bullet \quad \bullet \\ | \quad | \\ \bullet \quad \bullet \\ | \quad | \\ \bullet \quad \bullet \\ | \quad | \\ \bullet \quad \bullet \end{array} + 3 \begin{array}{c} \bullet \\ | \\ \bullet \\ | \\ \bullet \end{array} + \begin{array}{c} \bullet \\ / \backslash \\ \bullet \quad \bullet \\ | \quad | \\ \bullet \quad \bullet \\ | \quad | \\ \bullet \quad \bullet \\ | \quad | \\ \bullet \quad \bullet \end{array} + 2 \begin{array}{c} \bullet \\ | \\ \bullet \\ | \\ \bullet \end{array} + 2 \begin{array}{c} \bullet \\ / \backslash \\ \bullet \quad \bullet \\ | \quad | \\ \bullet \quad \bullet \\ | \quad | \\ \bullet \quad \bullet \end{array} + \begin{array}{c} \bullet \\ | \\ \bullet \\ | \\ \bullet \\ | \\ \bullet \end{array} + 2 \begin{array}{c} \bullet \\ / \backslash \\ \bullet \quad \bullet \\ | \quad | \\ \bullet \quad \bullet \\ | \quad | \\ \bullet \quad \bullet \end{array} + \begin{array}{c} \bullet \\ / \backslash \\ \bullet \quad \bullet \\ | \quad | \\ \bullet \quad \bullet \\ | \quad | \\ \bullet \quad \bullet \end{array} + \begin{array}{c} \bullet \\ | \\ \bullet \\ | \\ \bullet \\ | \\ \bullet \end{array} + \dots$$

Let  $f(h) \in K[[h]]$ . The homogeneous components of the unique solution of the combinatorial Dyson-Schwinger equation associated to  $f(h)$  generate a subalgebra of  $H_R$  denoted by  $H_f$ .

$H_f$  is not always a Hopf subalgebra

For example, for  $f(h) = 1 + h + h^2 + 2h^3 + \dots$ , then:

$$X = \bullet + \begin{array}{c} | \\ \bullet \end{array} + \begin{array}{c} \vee \\ \bullet \end{array} + \begin{array}{c} | \\ | \\ \bullet \end{array} + 2 \begin{array}{c} \vee \\ \vee \\ \bullet \end{array} + 2 \begin{array}{c} | \\ \vee \\ \bullet \end{array} + \begin{array}{c} \vee \\ \vee \\ \vee \\ \bullet \end{array} + \begin{array}{c} | \\ | \\ | \\ \bullet \end{array} + \dots$$

So:

$$\begin{aligned} \Delta(X(4)) = & X(4) \otimes 1 + 1 \otimes X(4) + (10X(1)^2 + 3X(2)) \otimes X(2) \\ & + (X(1)^3 + 2X(1)X(2) + X(3)) \otimes X(1) \\ & + X(1) \otimes (8 \begin{array}{c} \vee \\ \vee \\ \bullet \end{array} + 5 \begin{array}{c} | \\ | \\ \bullet \end{array}). \end{aligned}$$

If  $f(0) = 0$ , the unique solution of  $X = B(f(X))$  is 0. From now, up to a normalization we shall assume that  $f(0) = 1$ .

## Theorem

Let  $f(h) \in K[[h]]$ , with  $f(0) = 1$ . The following assertions are equivalent:

- 1  $H_f$  is a Hopf subalgebra of  $H_R$ .
- 2 There exists  $(\alpha, \beta) \in K^2$  such that  $(1 - \alpha\beta h)f'(h) = \alpha f(h)$ .
- 3 There exists  $(\alpha, \beta) \in K^2$  such that  $f(h) = 1$  if  $\alpha = 0$  or  $f(h) = e^{\alpha h}$  if  $\beta = 0$  or  $f(h) = (1 - \alpha\beta h)^{-\frac{1}{\beta}}$  if  $\alpha\beta \neq 0$ .

$1 \implies 2$ . We put  $f(h) = 1 + p_1 h + p_2 h^2 + \dots$ . Then  $X(1) = \dots$   
Let us write:

$$\Delta(X(n+1)) = X(n+1) \otimes 1 + 1 \otimes X(n+1) + X(1) \otimes Y(n) + \dots$$

- 1 By definition of the coproduct,  $Y(n)$  is obtained by cutting a leaf in all possible ways in  $X(n+1)$ . So it is a linear span of trees of degree  $n$ .
- 2 As  $H_f$  is a Hopf subalgebra,  $Y(n)$  belongs to  $H_f$ .

Hence, there exists a scalar  $\lambda_n$  such that  $Y(n) = \lambda_n X_n$ .

## lemma

Let us write:

$$X = \sum_t a_t t.$$

For any rooted tree  $t$ :

$$\lambda_{|t|} a_t = \sum_{t'} n(t, t') a_{t'},$$

where  $n(t, t')$  is the number of leaves of  $t'$  such that the cut of this leaf gives  $t$ .

We here assume that  $f$  is not constant. We can prove that  $p_1 \neq 0$ .

For  $t$  the ladder  $(B)^n(1)$ , we obtain:

$$p_1^{n-1} \lambda_n = 2(n-1)p_1^{n-2} p_2 + p_1^n.$$

Hence:

$$\lambda_n = 2 \frac{p_2}{p_1} (n-1) + p_1.$$

We put  $\alpha = p_1$  and  $\beta = 2 \frac{p_2}{p_1^2} - 1$ , then:

$$\lambda_n = \alpha(1 + (n-1)(1 + \beta)).$$

For  $t$  the corolla  $B(\cdot^{n-1})$ , we obtain:

$$\lambda_n p_{n-1} = n p_n + (n-1) p_{n-1} p_1.$$

Hence:

$$\alpha(1 + (n-1)\beta) p_{n-1} = n p_n.$$

Summing:

$$(1 - \alpha\beta h) f'(h) = \alpha f(h).$$

$$X(1) = \bullet,$$

$$X(2) = \alpha \downarrow,$$

$$X(3) = \alpha^2 \left( \frac{(1+\beta)}{2} \vee + \downarrow\downarrow \right),$$

$$X(4) = \alpha^3 \left( \frac{(1+2\beta)(1+\beta)}{6} \vee\vee + (1+\beta) \downarrow\vee + \frac{(1+\beta)}{2} \vee\downarrow + \downarrow\downarrow\downarrow \right),$$

$$X(5) = \alpha^4 \left( \begin{aligned} & \frac{(1+3\beta)(1+2\beta)(1+\beta)}{24} \vee\vee\vee + \frac{(1+2\beta)(1+\beta)}{2} \downarrow\vee\vee \\ & + \frac{(1+\beta)^2}{2} \vee\vee\downarrow + (1+\beta) \downarrow\vee\downarrow + \frac{(1+2\beta)(1+\beta)}{6} \vee\downarrow\downarrow \\ & + \frac{(1+\beta)}{2} \downarrow\downarrow\downarrow + (1+\beta) \downarrow\vee\downarrow + \frac{(1+\beta)}{2} \vee\downarrow\downarrow + \downarrow\downarrow\downarrow\downarrow \end{aligned} \right).$$

## Particular cases

- If  $(\alpha, \beta) = (1, -1)$ ,  $f = 1 + h$  and  $X(n) = (B)^n(1)$  for all  $n$ .
- If  $(\alpha, \beta) = (1, 1)$ ,  $f = (1 - h)^{-1}$  and:

$$X(n) = \sum_{|t|=n} \#\{\text{embeddings of } t \text{ in the plane}\} t.$$

- Si  $(\alpha, \beta) = (1, 0)$ ,  $f = e^h$  and:

$$X(n) = \sum_{|t|=n} \frac{1}{\#\{\text{symmetries of } t\}} t.$$
