## Linking first occurrence polynomials over $\mathbb{F}_p$ by Steenrod operations

PHAM ANH MINH  
GRANT WALKER

**Abstract** This paper provides analogues of the results of [16] for odd primes  $p$ . It is proved that for certain irreducible representations  $L(\lambda)$  of the full matrix semigroup  $M_n(\mathbb{F}_p)$ , the first occurrence of  $L(\lambda)$  as a composition factor in the polynomial algebra  $\mathbf{P} = \mathbb{F}_p[x_1, \dots, x_n]$  is linked by a Steenrod operation to the first occurrence of  $L(\lambda)$  as a submodule in  $\mathbf{P}$ . This operation is given explicitly as the image of an admissible monomial in the Steenrod algebra  $\mathcal{A}_p$  under the canonical anti-automorphism  $\chi$ . The first occurrences of both kinds are also linked to higher degree occurrences of  $L(\lambda)$  by elements of the Milnor basis of  $\mathcal{A}_p$ .

**Keywords** Steenrod algebra, anti-automorphism,  $p$ -truncated polynomial algebra  $\mathbf{T}$ ,  $\mathbf{T}$ -regular partition/representation

### 1 Introduction

Our aim is to obtain results corresponding to those of [16] for the case where the prime  $p > 2$ . In this we are only partly successful. The main theorem of [16] gives a Steenrod operation which links the first occurrence of each irreducible representation  $L(\lambda)$  of the full matrix semigroup  $M_n(\mathbb{F}_2)$  in the polynomial algebra  $\mathbf{P} = \mathbb{F}_2[x_1, \dots, x_n]$  with the first occurrence of  $L(\lambda)$  as a submodule in  $\mathbf{P}$ . Here  $M_n(\mathbb{F}_2)$  acts on  $\mathbf{P}$  on the right by linear substitutions, which commute with the action of the Steenrod algebra  $\mathcal{A}_2$  on  $\mathbf{P}$  on the left. By ‘first occurrence’ we have in mind the decomposition  $\mathbf{P} = \sum_{d \geq 0} \mathbf{P}^d$ , where  $\mathbf{P}^d$  is the module of homogeneous polynomials of total degree  $d$ , and the known facts that there are minimum degrees  $d_c(\lambda)$  and  $d_s(\lambda)$  in which  $L(\lambda)$  occurs, uniquely in each case, as a composition factor and as a submodule respectively.

For an odd prime  $p$ , we have again the commuting actions of  $M_n = M_n(\mathbb{F}_p)$  on the right of the polynomial algebra  $\mathbf{P} = \mathbb{F}_p[x_1, \dots, x_n]$  and the algebra  $\mathcal{A}_p$

of Steenrod  $p$ th powers (no Bocksteins) on the left. We refer to  $\mathcal{A}_p$ , somewhat inaccurately, as the Steenrod algebra, and grade it so that  $P^r$  raises degree by  $r(p-1)$ . There are  $p^n$  isomorphism classes of irreducible  $\mathbb{F}_p[M_n]$ -modules  $L(\lambda)$ , indexed by partitions  $\lambda = (\lambda_1, \lambda_2, \dots, \lambda_n)$ , which are column  $p$ -regular, i.e.  $0 \leq \lambda_i - \lambda_{i+1} \leq p-1$  for  $1 \leq i \leq n$ , where  $\lambda_{n+1} = 0$  [8, 9, 10]. The problem solved in [16] is certainly more difficult in this context. The submodule degree  $d_s(\lambda)$  has recently been determined [12] for every irreducible representation  $L(\lambda)$  of  $M_n$ , but  $d_c(\lambda)$  is not known in general. In particular, the first occurrence problem appears to be difficult even for the 1-dimensional representations  $\det^k$ ,  $1 \leq k \leq p-3$ ,  $p > 3$ , see [2, 3], although it is solved for  $\det^{p-2}$  [1]. (The partition indexing  $\det^k$  is  $(k, \dots, k) = (k^n)$ , i.e.  $k$  repeated  $n$  times.) Further, it is not known in general whether  $\mathbf{P}^{d_c(\lambda)}$  has a unique composition factor isomorphic to  $L(\lambda)$ . Here we identify a class of irreducible representations  $L(\lambda)$  which behave systematically. Since they arise naturally by considering tensor powers of the  $p$ -truncated polynomial algebra  $\mathbf{T} = \mathbf{P}/(x_1^p, \dots, x_n^p)$ , we call them  $\mathbf{T}$ -regular.

Our main result, Theorem 5.7, gives a Steenrod operation  $\theta(\lambda)$  which links the first occurrence and the first submodule occurrence in  $\mathbf{P}$  of a  $\mathbf{T}$ -regular  $L(\lambda)$ . This determines  $d_c(\lambda)$  in the  $\mathbf{T}$ -regular case. The operation  $\theta(\lambda)$  is given explicitly as the image of an admissible monomial under the canonical anti-automorphism  $\chi$  of  $\mathcal{A}_p$ . Calculations for  $n \leq 3$  suggest that such an operation  $\theta(\lambda)$  may exist for every irreducible representation  $L(\lambda)$  of  $M_n$ , but we do not pursue this here. Tri [14] has given an ‘algebraic’ alternative to this ‘topological’ method of finding  $d_c(\lambda)$ , using coefficient functions of  $\mathbb{F}_p[M_n]$ -modules.

For  $p = 2$ ,  $\mathbf{T}$  may be identified with the exterior algebra  $\Lambda(x_1, \dots, x_n)$ , and all the irreducible representations  $L(\lambda)$  of  $M_n$  are  $\mathbf{T}$ -regular. For  $p > 2$ , the only irreducible 1-dimensional  $\mathbf{T}$ -regular representations of  $M_n$  are the ‘trivial’ representation, in which all matrices act as 1, and the  $\det^{p-1}$  representation, in which non-singular matrices act as 1 and singular matrices as 0. The ‘trivial’ representation, for which  $\lambda = (0)$ , occurs in  $\mathbf{P}$  only as  $\mathbf{P}^0$ , the constant polynomials. Our key example is the  $\det^{p-1}$  representation. This occurs first as a composition factor as the top degree  $\mathbf{T}^{n(p-1)}$  of  $\mathbf{T}$ , where it is generated by the monomial  $(x_1 x_2 \cdots x_n)^{p-1}$  modulo  $p$ th powers, and first as a submodule in degree  $p_n = (p^n - 1)/(p - 1)$ , where it is generated by the Vandermonde determinant

$$w(n) = \begin{vmatrix} x_1 & x_2 & \cdots & x_n \\ x_1^p & x_2^p & \cdots & x_n^p \\ \vdots & \vdots & \ddots & \vdots \\ x_1^{p^{n-1}} & x_2^{p^{n-1}} & \cdots & x_n^{p^{n-1}} \end{vmatrix}.$$

**Theorem 1.1** *Let  $\chi$  be the canonical anti-isomorphism of  $\mathcal{A}_p$ . Then for  $n \geq 1$ ,*

$$\chi(P^{p^n-n})(x_1x_2 \cdots x_n)^{p-1} = w(n)^{p-1},$$

where  $p_n = (p^n - 1)/(p - 1)$ .

This result is true for  $p = 2$  if we interpret  $P^r$  as  $Sq^r$  [16]. The operation  $\chi(P^{p^n-n})$  may be replaced by the admissible monomial  $P^{p^{n-1}-1} \cdots P^{p^2-1} P^{p-1}$ , which is identical to the Milnor basis element  $P(p - 1, \dots, p - 1)$  of length  $n - 1$  (see Proposition 3.2). In general the operation  $\chi(P^{r_1}P^{r_2} \cdots P^{r_m})$  used in Theorem 5.7 can not be replaced by an admissible monomial or a Milnor basis element.

The structure of the paper is as follows. Section 2 contains basic facts about the action of  $\chi(P^r)$  and Milnor basis elements on polynomials. Section 3 contains independent proofs of Theorem 1.1 using invariant theory and by direct computation. In Section 4 we introduce the class of **T**-regular partitions to which our main results apply, and extend Theorem 1.1 to  $\mathbf{T}^d$  for all  $d$ . The main results are stated in Section 5 and proved in Section 6. Section 7 relates these results to the  $\mathbb{F}_p[M_n]$ -module structure of  $\mathbf{P}$ . Section 8 gives Milnor basis elements which link the first occurrence and (in certain cases) the first submodule occurrence of a **T**-regular representation of  $M_n$  with submodules in higher degrees.

The remarks which follow are intended to place our results in topological, combinatorial and algebraic contexts. As for topology, recall (e.g. [17]) that there is an  $\mathcal{A}_p$ -module decomposition  $\mathbf{P} = \bigoplus_{\lambda} \delta(\lambda)\mathbf{P}(\lambda)$ , where the  $\lambda$ -isotypical summand  $\mathbf{P}(\lambda)$  is an indecomposable  $\mathcal{A}_p$ -module, and where  $\delta(\lambda) = \dim L(\lambda)$ , the dimension of  $L(\lambda)$ . Identifying  $\mathbf{P}$  with the cohomology algebra  $H^*(\mathbb{C}P^\infty \times \cdots \times \mathbb{C}P^\infty; \mathbb{F}_p)$ , this decomposition can be realized (after localization at  $p$ ) by a homotopy equivalence  $\Sigma(\mathbb{C}P^\infty \times \cdots \times \mathbb{C}P^\infty) \sim \bigvee_{\lambda} \delta(\lambda)Y_{\lambda}$ , which splits the suspension of the product of  $n$  copies of infinite complex projective space  $\mathbb{C}P^\infty$  as a topological sum of spaces  $Y_{\lambda}$  such that  $H^*(Y_{\lambda}; \mathbb{F}_p) = \Sigma\mathbf{P}(\lambda)$ . The family of  $\mathcal{A}_p$ -modules  $\mathbf{P}(\lambda)$  is of major interest in algebraic topology. From this point of view, we determine the connectivity of  $Y_{\lambda}$  for **T**-regular  $\lambda$  (Corollary 5.8) and find a nonzero cohomology operation  $\theta(\lambda)$  on its bottom class (Theorem 5.7).

As for combinatorics and algebra, our aim is to provide information relating the  $\mathcal{A}_p$ -module structure of  $\mathbf{P}(\lambda)$  to combinatorial properties of  $\lambda$  and representation theoretic properties of  $L(\lambda)$ . The operation  $\theta(\lambda)$  and its source and target polynomials are combinatorially determined by  $\lambda$ . The target polynomial is

defined by  $w(\lambda') = \prod_{j=1}^{\lambda_1} w(\lambda'_j)$ , where  $\lambda'$  is the conjugate of  $\lambda$ , so that  $w(\lambda')$  is a product of determinants corresponding to the columns of the diagram of  $\lambda$ . This polynomial has already appeared in various forms in the literature. In Green's description [8, (5.4d)] of the highest weight vector of the dual Weyl module  $H^0(\lambda)$ ,  $w(\lambda')$  appears as a 'bideterminant' in the coordinate ring of  $M_n(K)$ , where  $K$  is an infinite field of characteristic  $p$ . A proof that  $w(\lambda')$  generates a submodule of  $\mathbf{P}^{d_s(\lambda)}$  isomorphic to  $L(\lambda)$  was given in [7, Proposition 1.3], and a proof that this is the first occurrence of  $L(\lambda)$  as a submodule in  $\mathbf{P}$  was given in [12].

We would like to thank the referee of this paper for a very careful reading and for a number of helpful suggestions.

## 2 Preliminary results

In this section we use variants of the Cartan formula  $P^r(fg) = \sum_{r=s+t} P^s f \cdot P^t g$  to study the action on polynomials of the elements  $\chi(P^r)$  and Milnor basis elements  $P(R)$  in the Steenrod algebra  $\mathcal{A}_p$ . We begin with the standard formula

$$P^i(x^{p^b}) = \begin{cases} x^{p^{b+1}} & \text{if } i = p^b, \\ 0 & \text{otherwise for } i > 0. \end{cases} \quad (1)$$

In particular, we wish to evaluate Steenrod operations on Vandermonde determinants of the form

$$[x_{i_1}^{s_1}, x_{i_2}^{s_2}, \dots, x_{i_n}^{s_n}] = \begin{vmatrix} x_{i_1}^{s_1} & x_{i_2}^{s_1} & \dots & x_{i_n}^{s_1} \\ x_{i_1}^{s_2} & x_{i_2}^{s_2} & \dots & x_{i_n}^{s_2} \\ \vdots & \vdots & \ddots & \vdots \\ x_{i_1}^{s_n} & x_{i_2}^{s_n} & \dots & x_{i_n}^{s_n} \end{vmatrix},$$

where the exponents  $s_1, \dots, s_n$  are powers of  $p$ . As above, we shall abbreviate such determinants by listing their diagonal entries in square brackets: in particular,  $w(n) = [x_1, x_2^p, \dots, x_n^{p^{n-1}}]$ . As in Theorem 1.1, we write  $p_n = (p^n - 1)/(p - 1)$ , so that  $p_0 = 0$  and  $p_n - p_j = (p^n - p^j)/(p - 1)$ . The following result is a straightforward calculation using the Cartan formula and (1).

**Lemma 2.1** *If  $r = p_n - p_j$ ,  $0 \leq j \leq n$ , then*

$$P^r w(n) = [x_1, x_2^p, \dots, x_j^{p^{j-1}}, x_{j+1}^{p^{j+1}}, \dots, x_n^{p^n}],$$

and  $P^r w(n) = 0$  otherwise. In particular,  $P^r w(n) = 0$  for  $0 < r < p^{n-1}$ .  $\square$

To simplify signs, we usually write  $\widehat{P}^r$  for  $(-1)^r \chi(P^r)$ . Thus if  $v$  is one of the generators  $x_i$  of  $\mathbf{P}$ , or more generally any linear form  $v = \sum_{i=1}^n a_i x_i$  in  $\mathbf{P}^1$ ,

$$\widehat{P}^r v = \begin{cases} v^{p^b} & \text{if } r = p^b, b \geq 0, \\ 0 & \text{otherwise.} \end{cases} \tag{2}$$

Formula (2) follows from (1) by using the identity  $\sum_{i+j=r} (-1)^i P^i \widehat{P}^j = 0$  in  $\mathcal{A}_p$  and induction on  $r$ . Using the identity  $\sum_{i+j=r} (-1)^i \widehat{P}^i P^j = 0$  and induction on  $k$ , (2) can be generalized to

$$\widehat{P}^r x^{p^k} = \begin{cases} x^{p^b} & \text{if } r = p^b - p^k, b \geq k, \\ 0 & \text{otherwise.} \end{cases} \tag{3}$$

This leads to the following generalization of [16, Lemma 2.2].

**Lemma 2.2**

$$\widehat{P}^r [x_1^{p^k}, x_2^{p^{k+1}}, \dots, x_n^{p^{k+n-1}}] = \begin{cases} [x_1^{p^k}, \dots, x_{n-1}^{p^{k+n-2}}, x_n^{p^b}] & \text{if } r = p^b - p_{k+n-1}, \\ 0 & \text{otherwise.} \end{cases}$$

The modifications required to the proof given in [16] are straightforward. □

In evaluating the operations  $\widehat{P}^r$ , we shall frequently make use of the Cartan formula expansion for polynomials  $f, g \in \mathbf{P}$ :

$$\widehat{P}^r (fg) = \sum_{s+t=r} \widehat{P}^s f \cdot \widehat{P}^t g, \tag{4}$$

which holds because  $\chi$  is a coalgebra homomorphism.

**Lemma 2.3** For all polynomials  $f, g$  in  $\mathbf{P}$  and all  $r \geq 0$ ,

$$\widehat{P}^r (f^p g) = \sum_{r=ps+t} (\widehat{P}^s f)^p \widehat{P}^t g.$$

**Proof** By (4) it suffices to prove the case  $g = 1$ , i.e.

$$\widehat{P}^r f^p = \begin{cases} (\widehat{P}^s f)^p & \text{if } r = ps, \\ 0 & \text{if } r \text{ is not divisible by } p. \end{cases}$$

In this case, the Cartan formula (4) gives  $\widehat{P}^r f^p = \sum \widehat{P}^{r_1} f \cdots \widehat{P}^{r_p} f$ , where the sum is over all ordered decompositions  $r = \sum_{i=1}^p r_i, r_i \geq 0$ . Except in the case where  $r_1 = \dots = r_p = s$ , cyclic permutation of  $r_1, \dots, r_p$  gives  $p$  equal terms which cancel in the sum. □

We write  $\alpha(k)$  for the sum of the digits in the base  $p$  expansion of a positive integer  $k$ , i.e. if  $k = \sum_{i \geq 0} a_i p^i$  where  $0 \leq a_i \leq p - 1$ , then  $\alpha(k) = \sum_{i \geq 0} a_i$ . Thus  $\alpha(k)$  is the minimum number of powers of  $p$  which have sum  $k$ , and  $\alpha(k) \equiv k \pmod{p - 1}$ . Formula (2) leads to the following simple sufficient condition for the vanishing of  $\widehat{P}^r$  on a homogeneous polynomial of degree  $d$ .

**Lemma 2.4** *If  $\alpha(r(p - 1) + d) > d$ , then  $\widehat{P}^r f = 0$  for all  $f \in \mathbf{P}^d$ .*

**Proof** Since the action of  $\widehat{P}^r$  is linear and commutes with specialization of the variables, it is sufficient to prove this when  $f = x_1 x_2 \cdots x_d$ . By (4)  $\widehat{P}^r f = \sum \widehat{P}^{r_1} x_1 \widehat{P}^{r_2} x_2 \cdots \widehat{P}^{r_d} x_d$ , where the sum is over all ordered decompositions  $r = r_1 + r_2 + \cdots + r_d$  with  $r_1, r_2, \dots, r_d \geq 0$ . By (2), the only non-zero terms are those in which  $r_i = p k_i$  for some non-negative integers  $k_1, k_2, \dots, k_d$ . But then  $r(p - 1) + d = \sum_i p k_i$ , and the result follows by definition of  $\alpha$ .  $\square$

**Lemma 2.5** *Let  $k \geq 0$  and let  $v = \sum_{i=1}^n a_i x_i$  be a linear form in  $\mathbf{P}^1$ . Then*

$$\widehat{P}^{p^k - 1} v^{p-1} = v^{p^k(p-1)}.$$

**Proof** There is a unique way to write  $p^k - 1$  as the sum of  $p - 1$  integers of the form  $p_i$  for  $i \geq 0$ , namely  $p^k - 1 = (p - 1)p_k$ . The result now follows from (2) and the Cartan formula (4).  $\square$

**Remark 2.6** The same method can be used to evaluate  $\widehat{P}^r v^{p-1}$  for all  $r$ . The result is

$$\widehat{P}^r v^{p-1} = \begin{cases} c_r v^{(r+1)(p-1)} & \text{if } \alpha((r + 1)(p - 1)) = p - 1, \\ 0 & \text{otherwise,} \end{cases}$$

where if  $(r + 1)(p - 1) = j_1 p^{a_1} + \cdots + j_s p^{a_s}$ , with  $a_1 > \cdots > a_s \geq 0$  and  $\sum_{i=1}^s j_i = p - 1$ , then  $c_r = (p - 1)! / (j_1! j_2! \cdots j_s!)$ .

The following result, the ‘Cartan formula for Milnor basis elements’ is well-known (cf. [16, Lemma 5.3]).

**Lemma 2.7** *For a Milnor basis element  $P(R) = P(r_1, \dots, r_n)$  and polynomials  $f, g \in \mathbf{P}$ ,*

$$P(R)(fg) = \sum_{R=S+T} P(S)f \cdot P(T)g,$$

where the sum is over all sequences  $S = (s_1, \dots, s_n)$  and  $T = (t_1, \dots, t_n)$  of non-negative integers such that  $r_i = s_i + t_i$  for  $1 \leq i \leq n$ .  $\square$

In the same way as for Lemma 2.3, this gives the following result.

**Lemma 2.8** *Let  $P(R) = P(r_1, \dots, r_n)$  be a Milnor basis element and let  $f, g \in \mathbf{P}$  be polynomials. Then*

$$P(R)(f^p g) = \sum_{R=pS+T} (P(S)f)^p \cdot P(T)g. \quad \square$$

Here  $R = pS + T$  means that  $r_i = ps_i + t_i$  for  $1 \leq i \leq n$ .

### 3 The $\det^{p-1}$ representation

In this section we give three proofs of Theorem 1.1. The first uses the results of [12] on submodules, while the second is a variant of this which uses only classical invariant theory. The third proof is computational. The first two proofs use the following preliminary result, which shows that the operation  $\widehat{P}^{p_n-n}$  maps to 0 all monomials of degree  $n(p-1)$  other than the generating monomial  $(x_1 x_2 \cdots x_n)^{p-1}$  for  $\det^{p-1}$ .

**Lemma 3.1** *Let  $f$  be a polynomial in  $\mathbf{P}^{n(p-1)}$  which is divisible by  $x^p$  for some variable  $x = x_i$ ,  $1 \leq i \leq n$ . Then  $\widehat{P}^{p_n-n} f = 0$ .*

**Proof** Let  $f = x^p g$ , where  $g \in \mathbf{P}$ . Then by Lemma 2.3

$$\widehat{P}^{p_n-n} f = \sum_{p_n-n=ps+t} (\widehat{P}^s x)^p \widehat{P}^t g. \quad (5)$$

By (2),  $\widehat{P}^s x = 0$  if  $s \neq p_k$  for some  $k$  with  $0 \leq k \leq n-2$ . Thus it is sufficient to prove that  $\widehat{P}^t g = 0$  for  $t = p_n - n - p \cdot p_k$ , where  $g \in \mathbf{P}^{n(p-1)-p}$ . By Lemma 2.4, this holds when  $\alpha((t+n)(p-1) - p) > n(p-1) - p$ . Now  $(t+n)(p-1) - p = p_n(p-1) - p \cdot p_k(p-1) - p = p^n - p^{k+1} - 1$ , hence  $\alpha((t+n)(p-1) - p) = n(p-1) - 1 > n(p-1) - p$  as required. Thus  $\widehat{P}^t g = 0$  in all terms of (5) in which  $\widehat{P}^s x \neq 0$ , and so  $\widehat{P}^{p_n-n} f = 0$ .  $\square$

**First Proof of Theorem 1.1** We first show that the monomial  $m = (x_1 x_2^p \cdots x_n^{p^{n-1}})^{p-1}$  appears in  $\widehat{P}^{p_n-n}(x_1 \cdots x_n)^{p-1}$  with coefficient 1. In the Cartan formula expansion (4),  $m$  can appear only in the term arising from the decomposition  $p_n - n = r_1 + r_2 + \cdots + r_n$ , where  $r_k = p^{k-1} - 1$  for  $1 \leq k \leq n$ . By Lemma 2.5,  $m$  appears in this term with coefficient 1.

By Lemma 3.1,  $\widehat{P}^{p_n-n}$  maps all other monomials in degree  $n(p-1)$  to 0. Hence  $\widehat{P}^{p_n-n}(x_1 \cdots x_n)^{p-1}$  generates a 1-dimensional  $\mathbb{F}_p[M_n]$ -submodule of  $\mathbf{P}^{p^n-1}$ . Since  $(x_1 \cdots x_n)^{p-1}$  generates the 1-dimensional quotient  $\mathbf{T}^{n(p-1)}$  of  $\mathbf{P}^{n(p-1)}$  and since  $\mathbf{T}^{n(p-1)} \cong \det^{p-1}$ , this submodule of  $\mathbf{P}^{p^n-1}$  is also isomorphic to  $\det^{p-1}$ .

It is known [12] that the first submodule occurrence of  $\det^{p-1}$  for  $M_n$  in  $\mathbf{P}$  is generated by  $w(n)^{p-1}$ , and that this is the unique submodule occurrence of  $\det^{p-1}$  in degree  $p^n - 1$ . Since  $m$  is the product of the leading diagonal terms in  $w(n)^{p-1} = [x_1, x_2^p, \dots, x_n^{p^{n-1}}]^{p-1}$ ,  $m$  also has coefficient 1 in  $w(n)^{p-1}$ .  $\square$

**Second Proof of Theorem 1.1** We recall that  $D(n, p)$  is the ring of  $GL_n(\mathbb{F}_p)$ -invariants in  $\mathbf{P}$ , and that it is a polynomial algebra over  $\mathbb{F}_p$  with generators  $Q_{n,i}$  in degree  $p^n - p^i$  for  $0 \leq i \leq n - 1$ . We may identify  $Q_{n,0}$  with  $w(n)^{p-1}$ . Since  $\mathbf{T}^{n(p-1)}$  is isomorphic to the trivial  $GL_n(\mathbb{F}_p)$ -module, it follows as in our first proof that  $\widehat{P}^{p_n-n}(x_1 \cdots x_n)^{p-1} \in D(n, p)$ .

We shall prove that  $w(n)$  divides  $\widehat{P}^{p_n-n}(x_1 \cdots x_n)^{p-1}$ . Recall that  $w(n)$  is the product of linear factors  $c_1x_1 + \dots + c_nx_n$ , where  $c_1, \dots, c_n \in \mathbb{F}_p$ . If we specialize the variables in  $(x_1 \cdots x_n)^{p-1}$  by imposing the relation  $c_1x_1 + \dots + c_nx_n = 0$ , then every monomial in the resulting polynomial is divisible by  $x^p$  for some variable  $x = x_i$ . By Lemma 3.1, such a monomial is in the kernel of  $\widehat{P}^{p_n-n}$ . Thus  $\widehat{P}^{p_n-n}(x_1 \cdots x_n)^{p-1}$  is divisible by  $c_1x_1 + \dots + c_nx_n$ , and so it is divisible by  $w(n)$ .

Now an element of  $D(n, p)$  in degree  $p^n - 1$  which is divisible by  $w(n)$  must be a scalar multiple of  $Q_{n,0} = w(n)^{p-1}$ . For if a polynomial in the remaining generators  $Q_{n,1}, \dots, Q_{n,n-1}$  of  $D(n, p)$  is divisible by  $w(n)$ , the quotient would be  $SL_n(\mathbb{F}_p)$ -invariant, giving a non-trivial polynomial relation between  $Q_{n,1}, \dots, Q_{n,n-1}$  and  $w(n)$ . This contradicts Dickson's theorem that these are algebraically independent generators of the polynomial algebra of  $SL_n(\mathbb{F}_p)$ -invariants in  $\mathbf{P}$ .  $\square$

Our third proof of Theorem 1.1 is by direct calculation. We shall evaluate the Milnor basis element  $P(p-1, \dots, p-1)$  of length  $n-1$  on  $(x_1 \cdots x_n)^{p-1}$ . The following result relates the element  $P(p-1, \dots, p-1, b)$  of length  $n$  to admissible monomials and to the anti-automorphism  $\chi$ . In particular, we show that  $P(p-1, \dots, p-1)$  and  $\widehat{P}^{p_n-n}$  have the same action on  $(x_1 \cdots x_n)^{p-1}$ .

**Proposition 3.2** For  $1 \leq b \leq p-1$ ,

$$(i) \quad P(p-1, \dots, p-1, b) = P^{(b+1)p^{n-1}-1} \dots P^{(b+1)p-1} P^b \text{ for } n \geq 1,$$

- (ii)  $\widehat{P}^{(b+1)p_n-n}g = P(p-1, \dots, p-1, b)g$  if  $\deg g \leq n(p-1) + b$  for  $n \geq 1$ ,
- (iii)  $\widehat{P}^{(b+1)p_n-n} = P^{(b+1)p^{n-1}}\widehat{P}^{(b+1)p_{n-1}-n} + P(p-1, \dots, p-1, b)$  for  $n \geq 2$ .

**Proof** Statement (i) is a special case of [4, Theorem 1.1]. For (ii), recall [11] that  $\widehat{P}^d$  is the sum of all Milnor basis elements  $P(R)$  in degree  $d(p-1)$ . Here  $R = (r_1, r_2, \dots)$  is a finite sequence of non-negative integers, and  $P(R)$  has degree  $|R| = \sum (p^i - 1)r_i$  and excess  $e(R) = \sum r_i$ . In particular,  $P^d = P(d)$  is the unique Milnor basis element of maximum excess  $d$  in degree  $d(p-1)$ , but in general there may be more than one element of minimum excess in a given degree.

We will show that  $P(p-1, \dots, p-1, b)$  is the unique element of minimum excess  $e = (n-1)(p-1) + b$  in degree  $d(p-1)$  when  $d = (b+1)p_n - n$ . By [11, Lemma 8] a bijection  $P(r_1, r_2, \dots, r_m) \leftrightarrow P^{t_1}P^{t_2} \dots P^{t_m}$  between the Milnor basis and the admissible basis of  $\mathcal{A}_p$  is defined by  $t_m = r_m$  and  $t_i = r_i + pt_{i+1}$  for  $1 \leq i < m$ . This preserves both the degree and the excess. Thus it is equivalent to prove that  $m = P^{(b+1)p^{n-1}-1} \dots P^{(b+1)p-1}P^b$  is the unique admissible monomial of minimum excess in degree  $d(p-1)$ . Now the excess of an admissible monomial  $P^{t_1}P^{t_2} \dots P^{t_m}$  is  $pt_1 - d(p-1)$  where  $d = \sum_i t_i$ , and so it is minimal when  $t_1$  is minimal. It is easy to verify that  $m$  is the unique admissible monomial in degree  $d(p-1)$  for which  $t_1 = (b+1)p^{n-1} - 1$ , and that this value of  $t_1$  is minimal.

Note that  $p$  divides  $|R| + e(R)$  for all  $R$ . Hence  $\widehat{P}^{(b+1)p_n-n} - P(p-1, \dots, p-1, b)$  has excess  $> e + p - 1 = n(p-1) + b$ , and so  $\widehat{P}^{(b+1)p_n-n}g = P(p-1, \dots, p-1, b)g$  when  $g$  is a polynomial of degree  $\leq n(p-1) + b$ .

(iii) Recall Davis’s formula [5]

$$P^u \widehat{P}^v = \sum_{|R|=(p-1)(u+v)} \binom{|R| + e(R)}{pu} P(R), \tag{6}$$

which we may apply in the case  $u = (b+1)p^{n-1}$ ,  $v = (b+1)p_{n-1} - n$  to show that  $P^u \widehat{P}^v$  is the sum of all Milnor basis elements in degree  $d(p-1)$  other than the element  $P(p-1, \dots, p-1, b)$  of minimal excess.

For  $R = (p-1, \dots, p-1, b)$  we have  $|R| + e(R) = (b+1)p^n - p$ , and since  $pu = (b+1)p^n$  the coefficient in (6) is zero. Since  $p$  divides  $|R| + e(R)$  for all  $R$ ,  $|R| + e(R) \geq (b+1)p^n$  for all other  $R$  with  $|R| = d(p-1)$ . As remarked above, the unique element of maximal excess is  $P^d$  itself, and so for all  $R$  we have  $|R| + e(R) \leq pd = (b+1)(p + p^2 + \dots + p^n) - pn$ . It is clear from this inequality that the coefficient in (6) is 1 for all  $R \neq (p-1, \dots, p-1, b)$ .  $\square$

**Third Proof of Theorem 1.1** Let  $\theta_n = P^{p^n-1} \dots P^{p^2-1} P^{p-1}$  for  $n \geq 1$ , and  $\theta_0 = 1$ . We assume that  $\theta_{n-1}(x_1 \dots x_n)^{p-1} = w(n)^{p-1}$  as induction hypothesis on  $n$ , the case  $n = 1$  being trivial.

The cofactor expansion of  $w(n+1) = [x_1, x_2^p, \dots, x_{n+1}^{p^n}]$  by the top row gives  $w(n+1) = \sum_{i=1}^{n+1} (-1)^i x_i \Delta_i^p$ , where  $\Delta_i = [x_1, \dots, x_{i-1}^{p^{i-2}}, x_{i+1}^{p^{i-1}}, \dots, x_{n+1}^{p^{n-1}}]$ . Hence  $w(n+1) \cdot (x_1 \dots x_{n+1})^{p-1} = \sum_{i=1}^{n+1} (-1)^i x_i^p \Delta_i^p (x_1 \dots x_{i-1} x_{i+1} \dots x_{n+1})^{p-1}$ .

By Proposition 3.2(i),  $\theta_n = P(p-1, \dots, p-1)$  of length  $n$ , and so by Lemma 2.8  $\theta_n(w(n+1) \cdot (x_1 \dots x_{n+1})^{p-1}) = \sum_{i=1}^{n+1} (-1)^i x_i^p \Delta_i^p \theta_n(x_1 \dots x_{i-1} x_{i+1} \dots x_{n+1})^{p-1}$ . Since  $\theta_n = P^{p^n-1} \theta_{n-1}$ ,  $\theta_n(x_1 \dots x_{i-1} x_{i+1} \dots x_{n+1})^{p-1} = P^{p^n-1} \Delta_i^{p-1}$  by the induction hypothesis. Since  $\Delta_i^{p-1}$  has degree  $p^n - 1$ ,  $P^{p^n-1} \Delta_i^{p-1} = \Delta_i^{p(p-1)}$ . Hence  $\theta_n(w(n+1) \cdot (x_1 \dots x_{n+1})^{p-1}) = \sum_{i=1}^{n+1} (-1)^i x_i^p \Delta_i^{p^2} = w(n+1)^p$ .

By Lemma 2.1,  $P^r w(n+1) = 0$  for  $0 < r < p^n$ . As  $\theta_n = P^{p^n-1} \dots P^{p^2-1} P^{p-1}$ , iterated application of the Cartan formula gives  $\theta_n(w(n+1) \cdot (x_1 \dots x_{n+1})^{p-1}) = w(n+1) \cdot \theta_n(x_1 \dots x_{n+1})^{p-1}$ . Hence  $w(n+1) \cdot \theta_n(x_1 \dots x_{n+1})^{p-1} = w(n+1)^p$ . Cancelling the factor  $w(n+1)$ , the inductive step is proved.

### 4 T-regular partitions

In this section we define the special class of **T-regular** partitions, and extend Theorem 1.1 to give a Steenrod operation  $\widehat{P}^r$  which links the first occurrence and first submodule occurrence of  $\mathbf{T}^d$  for all  $d$ . In fact we prove a more general result which links the first occurrence to a family of higher degree occurrences.

The truncated polynomial module  $\mathbf{T}^d = \mathbf{P}^d / (\mathbf{P}^d \cap (x_1^p, \dots, x_n^p))$  has a  $\mathbb{F}_p$ -basis represented in  $\mathbf{P}^d$  by the set of all monomials  $x_1^{s_1} x_2^{s_2} \dots x_n^{s_n}$  of total degree  $d = \sum_i s_i$  with  $s_i < p$  for  $1 \leq i \leq n$ . By [2, Theorem 6.1]  $\mathbf{T}^d \cong L((p-1)^{n-1}b)$ , where  $d = (n-1)(p-1) + b$  and  $1 \leq b \leq p-1$ . We regard the corresponding diagram as a block of  $p-1$  columns, in which the first  $b$  columns have length  $n$  and the remaining  $p-b-1$  columns have length  $n-1$ . Given a partition  $\lambda$ , we can divide its diagram into  $m$  blocks of  $p-1$  columns and compare the blocks with the diagrams corresponding to these. (The  $m$ th block may have  $< p-1$  columns.) For  $1 \leq j \leq m$ , let  $\lambda_{(j)}$  be the partition whose diagram is the  $j$ th block, and let  $\gamma_j = \deg \lambda_{(j)}$  be the number of boxes in the  $j$ th block.

**Definition 4.1** A column  $p$ -regular partition  $\lambda$  is **T-regular** if  $L(\lambda_{(j)}) \cong \mathbf{T}^{\gamma_j}$  for all  $j$ . Equivalently, for all  $a \geq 1$ , there is at most one value of  $i$  for which  $(a-1)(p-1) < \lambda_i < a(p-1)$ . If  $\lambda$  is **T-regular**, we call  $\gamma$  the **T-conjugate** of  $\lambda$ .

In the case  $p = 2$ , all column 2-regular partitions are  $\mathbf{T}$ -regular, and  $\gamma = \lambda'$ , the conjugate of  $\lambda$ . If  $\kappa$  is column 2-regular, then the partition  $\lambda = (p - 1)\kappa$  obtained by multiplying each part of  $\kappa$  by  $p - 1$  is  $\mathbf{T}$ -regular. Since  $\lambda$  is column  $p$ -regular,  $\gamma_j - \gamma_{j+1} \geq p - 1$  for all  $j$ , and  $m \leq n$ . Thus there is a bijection  $\lambda \leftrightarrow \gamma$  between the set of  $\mathbf{T}$ -regular partitions  $\lambda = (\lambda_1, \dots, \lambda_n)$  and the set of partitions  $\gamma = (\gamma_1, \dots, \gamma_n)$  which satisfy  $\gamma_1 \leq n(p - 1)$  and  $\gamma_j - \gamma_{j+1} \geq p - 1$  for  $1 \leq j \leq n - 1$ . In terms of the Mullineux involution  $M$  on the set of all row  $p$ -regular partitions,  $\lambda$  and  $\gamma$  are related by  $M(\gamma) = \lambda'$  [15, Proposition 3.13].

We next extend Theorem 1.1 to give linking formulae for the representations  $\mathbf{T}^d$ . It will be convenient to introduce abbreviated notation for some further Vandermonde determinants. Let  $w(n, a) = [x_1, \dots, x_a^{p^{a-1}}, x_{a+1}^{p^{a+1}}, \dots, x_n^{p^n}]$  for  $0 \leq a \leq n$ , where the exponent  $p^a$  is omitted. In particular,  $w(n, n) = w(n)$  and  $w(n, 0) = w(n)^p$ .

**Proposition 4.2** For  $n \geq 1$  and  $1 \leq i \leq p - 1$ , let  $i = i_1 + \dots + i_s$  where  $i_1, \dots, i_s > 0$ , and let  $j = i_1 p_{a_1} + \dots + i_s p_{a_s}$ , where  $a_1 > \dots > a_s \geq 0$ . Then

$$\widehat{P}^{p_n - n - j} \left( (x_1 x_2 \dots x_{n-1})^{p-1} x_n^{p-i-1} \right) = (-1)^{i(n-1)-j} w(n)^{p-i-1} \cdot \prod_{r=1}^s w(n-1, a_r)^{i_r}.$$

Specializing to the case  $s = 1$ ,  $j = ip_{n-1}$  and putting  $b = p - 1 - i$ , we obtain an operation linking the first occurrence and the first submodule occurrence of the representation  $\mathbf{T}^d$ , as follows. Theorem 1.1 can be taken as the case  $b = 0$  or as the case  $b = p - 1$ ; we choose  $b = p - 1$  to fit notation later.

**Corollary 4.3** For  $n \geq 1$  and  $1 \leq b \leq p - 1$ ,

$$\widehat{P}^{(b+1)p_{n-1} - (n-1)} \left( (x_1 x_2 \dots x_{n-1})^{p-1} x_n^b \right) = w(n)^b \cdot w(n-1)^{p-b-1}.$$

**Proof of Proposition 4.2** We introduce a parameter into Theorem 1.1, by working in  $\mathbb{F}_p[x_1, \dots, x_{n+1}]$  and writing  $x_{n+1} = t$  in order to distinguish this variable. Since the action of  $\mathcal{A}_p$  commutes with the linear substitution which maps  $x_n$  to  $x_n + t$  and fixes  $x_i$  for  $i \neq n$ , we obtain

$$\widehat{P}^{p_n - n} (x_1 \dots x_{n-1} (x_n + t))^{p-1} = [x_1, x_2^p, \dots, x_{n-1}^{p^{n-2}}, (x_n + t)^{p^{n-1}}]^{p-1}. \tag{7}$$

Expanding the left hand side of (7) by the binomial theorem, we obtain

$$\sum_{i=0}^{p-1} (-1)^i \widehat{P}^{p_n - n} \left( (x_1 \dots x_{n-1})^{p-1} x_n^{p-1-i} t^i \right).$$

The right hand side of (7) is

$$[x_1, x_2^p, \dots, x_{n-1}^{p^{n-2}}, x_n^{p^{n-1}} + t^{p^{n-1}}]^{p-1} = \sum_{i=0}^{p-1} (-1)^i w(n)^{p-1-i} [x_1, x_2^p, \dots, x_{n-1}^{p^{n-2}}, t^{p^{n-1}}]^i,$$

since  $w(n) = [x_1, x_2^p, \dots, x_n^{p^{n-1}}]$ . The summands in (7) corresponding to  $i = 0$  give the original result, Theorem 1.1, and so are equal. In fact we can equate the  $i$ th summands for all  $i$ . This happens because  $\widehat{P}^r$  raises degree by  $r(p-1)$ , so that the powers  $t^k$  which occur in the  $i$ th summand on the left have  $k \equiv i \pmod{p-1}$ , while if  $t^k$  occurs in the  $i$ th summand on the right, then  $k$  is the sum of  $i$  powers of  $p$ , so that again  $k \equiv i \pmod{p-1}$ . Hence for  $1 \leq i \leq p-1$  we have

$$\widehat{P}^{p_n-n}((x_1 \cdots x_{n-1})^{p-1} x_n^{p^{n-1}-i} t^i) = w(n)^{p-1-i} \cdot [x_1, x_2^p, \dots, x_{n-1}^{p^{n-2}}, t^{p^{n-1}}]^i. \tag{8}$$

Since the powers  $t^k$  of  $t$  which can appear here are such that  $k$  is the sum of  $i$  powers of  $p$ , we can write  $k = i_1 p^{a_1} + \dots + i_s p^{a_s}$ , where  $a_1 > \dots > a_s \geq 0$  and  $i_1 + \dots + i_s = i$ . Using the expansion

$$[x_1, x_2^p, \dots, x_{n-1}^{p^{n-2}}, t^{p^{n-1}}] = \sum_{a=0}^{n-1} (-1)^{n-1-a} w(n-1, a) t^{p^a}$$

we can evaluate the coefficient of  $t^k$  on the right hand side of (8) as

$$(-1)^{i(n-1)-j} \frac{i!}{i_1! \cdots i_s!} w(n)^{p-1-i} \cdot w(n-1, a_1)^{i_1} \cdots w(n-s, a_s)^{i_s},$$

where we have simplified the sign by noting that  $a_1 i_1 + \dots + a_s i_s \equiv j \pmod{2}$  since  $p_a \equiv a \pmod{2}$ . By the Cartan formula (4), the left hand side of (8) is

$$\sum_{j=0}^{p_n-n} \widehat{P}^{p_n-n-j} ((x_1 \cdots x_{n-1})^{p-1} x_n^{p^{n-1}-i}) \cdot \widehat{P}^j t^i$$

Here the term in  $t^k$  arises from  $\widehat{P}^j t^i$  where  $k = j(p-1) + i$ , so that  $j = i_1 p_{a_1} + \dots + i_s p_{a_s}$ , and since this decomposition of  $j$  as a sum of at most  $i$  powers of  $p$  is unique, formulas (2) and (4) give  $\widehat{P}^j t^i = (i!/i_1! \cdots i_s!) t^k$ . Thus equating coefficients of  $t^k$  in (8) gives the result.

## 5 Linking for T-regular representations

In this section we state our main results. We fix an odd prime  $p$  and a positive integer  $n$  throughout. As in [16], our results will be statements about polynomials in  $n$  variables when  $\lambda$  has length  $n$ , i.e.  $\lambda$  has  $n$  nonzero parts. There

is no loss of generality, since the projection in  $M_n$  which sends  $x_n$  to 0 and  $x_i$  to  $x_i$  for  $i < n$  maps  $L(\lambda)$  to zero if  $\lambda_n > 0$  and on to the corresponding  $\mathbb{F}_p[M_{n-1}]$ -module  $L(\lambda)$  if  $\lambda_n = 0$  (cf. [2, Section 3]). Hence we shall always assume that  $\lambda_n \neq 0$ .

We first establish some notation. Given a  $\mathbf{T}$ -regular partition  $\lambda$  of length  $n$ , we define a polynomial  $v(\lambda)$  whose degree  $d_c(\lambda)$  is given by (9) and which ‘represents’  $L(\lambda)$ , in the sense that the submodule of  $\mathbf{P}^{d_c(\lambda)}$  generated by  $v(\lambda)$  has a quotient module isomorphic to  $L(\lambda)$ . We index the diagram of  $\lambda$  using matrix coordinates  $(i, j)$ , so that  $1 \leq i \leq n$  and  $1 \leq j \leq \lambda_i$ .

**Definition 5.1** *The  $k$ th antidiagonal of the diagram of  $\lambda$  is the set of boxes such that  $j + i(p - 1) = k + p - 1$ . If the lowest box is in row  $i$  and the highest is in row  $i - s + 1$ , let  $v_k(\lambda) = [x_{i-s+1}, x_{i-s+2}^p, \dots, x_i^{p^{s-1}}]$ , and let  $v(\lambda) = \prod_{k=1}^{\gamma_1} v_k(\lambda)$ .*

Thus an antidiagonal is the set of boxes which lie on a line of slope  $1/(p - 1)$  in the diagram, and  $v(\lambda)$  is a product of corresponding Vandermonde determinants. Indenting successive rows by  $p - 1$  columns, we obtain a shifted diagram whose columns correspond to these antidiagonals. The  $\mathbf{T}$ -conjugate  $\gamma$  of  $\lambda$  records the number of antidiagonals  $\gamma_s$  of length  $\geq s$  for all  $s \geq 1$ .

**Example 5.2** Let  $p = 5$ ,  $\lambda = (9, 6, 3)$ , so that  $\gamma = (11, 6, 1)$ . The shifted diagram

gives  $v(\lambda) = x_1^4 \cdot [x_1, x_2^5]^4 \cdot [x_1, x_2^5, x_3^{25}] \cdot [x_2, x_3^5] \cdot x_3$ .

Recall [12] that  $w(\lambda') = \prod_{j=1}^{\lambda_1} w(\lambda'_j)$  generates the first occurrence of  $L(\lambda)$  as a submodule in  $\mathbf{P}$ . Thus we can rewrite the linking theorem for  $\mathbf{T}^d$ , Corollary 4.3, as follows.

**Theorem 5.3** *Let  $d = (n - 1)(p - 1) + b$ , where  $n \geq 1$  and  $1 \leq b \leq p - 1$ , so that  $\mathbf{T}^d \cong L(\lambda)$  where  $\lambda = ((p - 1)^{n-1}b)$ . Then  $\widehat{P}^r v(\lambda) = w(\lambda')$ , where  $r = (b + 1)p_{n-1} - (n - 1)$  and  $p_{n-1} = (p^{n-1} - 1)/(p - 1)$ .  $\square$*

By the *leading monomial* of a polynomial we mean the monomial  $\prod_{i=1}^n x_i^{s_i}$  occurring in it (ignoring the nonzero coefficient) whose exponents are highest in left lexicographic order. The leading monomial  $s(\lambda)$  of  $v(\lambda)$  is obtained by

multiplying the principal antidiagonals in the determinants  $v_k(\lambda)$ ,  $1 \leq k \leq \gamma_1$ . (In Example 5.2,  $s(\lambda) = x_1^{49}x_2^{14}x_3^3$ .) The base  $p$  expansion of every exponent in  $s(\lambda)$  has the form  $s_i = c_k p^k + (p-1)p^{k-1} + \dots + (p-1)p + (p-1)$ , i.e.  $s_i \equiv -1 \pmod{p^k}$ , where  $p^k < s_i < p^{k+1}$ . We adapt the terminology introduced by Singer [13], by calling such a monomial a ‘spike’. In the case  $p = 2$ ,  $s(\lambda) = x_1^{2^{\lambda_1-1}} \dots x_n^{2^{\lambda_n-1}}$ . A polynomial which contains such a spike can not be ‘hit’, i.e. it can not be the image of a polynomial of lower degree under a Steenrod operation. This is easily seen by considering the 1-variable case. Hence the polynomial  $v(\lambda)$  is not hit.

**Proposition 5.4** *Let  $\lambda$  be  $\mathbf{T}$ -regular with  $\mathbf{T}$ -conjugate  $\gamma$ .*

- (i) *If  $\lambda_i = a_i(p-1) + b_i$ ,  $a_i \geq 0$ ,  $1 \leq b_i \leq p-1$ , then  $s(\lambda) = \prod_{i=1}^n x_i^{(b_i+1)p^{a_i-1}}$ .*
- (ii) *With  $\lambda_{(j)}$  as in Definition 4.1,  $s(\lambda) = v(\lambda_{(1)}) \cdot v(\lambda_{(2)})^p \cdots v(\lambda_{(m)})^{p^{m-1}}$ .*
- (iii) *The coefficient of  $s(\lambda)$  in  $v(\lambda)$  is  $(-1)^{\epsilon(\lambda)}$ , with  $\epsilon(\lambda) = \sum_{j=1}^{\lfloor m/2 \rfloor} (-1)^{j-1} \gamma_{2j}$ .*

**Proof** Formulae (i) and (ii) are easily read off from a tableau obtained by entering  $p^{j-1}$  in each box in the  $j$ th block of  $p-1$  columns of the diagram of  $\lambda$ , and reading this according to rows and to blocks of columns. For (iii), note that the sign of the term arising from the leading antidiagonal in the expansion of an  $s \times s$  determinant is  $+1$  for  $s \equiv 0, 1 \pmod{4}$  and  $-1$  for  $s \equiv 2, 3 \pmod{4}$ , and that the diagram of  $\lambda$  has  $\gamma_j$  antidiagonals of length  $\geq j$ . □

In Theorem 5.5 we establish (i) a ‘level 0 formula’, which gives a sufficient condition for  $\widehat{P}^r v(\lambda) = 0$ , and (ii) a ‘level 1 formula’, which gives a sufficient condition for  $\widehat{P}^r v(\lambda)$  to be a product related to the decomposition  $\lambda = \lambda_{(1)} + \lambda^-$  which splits off the first  $p-1$  columns of the diagram. Thus  $\lambda_{(1)} = ((p-1)^{n-1}b)$ , where  $\gamma_1 = (n-1)(p-1) + b$  and  $1 \leq b \leq p-1$ , and  $\lambda^-$  is defined by  $\lambda_i^- = \lambda_i - (p-1)$  if  $\lambda_i \geq p-1$ , and  $\lambda_i^- = 0$  otherwise. Our main linking result, Theorem 5.7, follows from Theorem 5.5 by induction on  $m$ , the length of  $\gamma$ . The proofs of Theorems 5.5 and 5.7 are deferred to Section 6.

**Theorem 5.5** *Let  $\lambda$  be  $\mathbf{T}$ -regular with  $\mathbf{T}$ -conjugate  $\gamma$ , let  $d_c$  be defined by (9) below, and let  $R(r, \lambda) = r(p-1) + d_c(\lambda) - d_c(\lambda^-)$ . Recall that  $\alpha(k)$  is the sum of the digits in the base  $p$  expansion of  $k$ .*

- (i) *If  $\alpha(R(r, \lambda)) > \gamma_1$ , then  $\widehat{P}^r v(\lambda) = 0$ .*
- (ii) *If  $\alpha(R(r, \lambda)) = \gamma_1$ , then  $\widehat{P}^r v(\lambda) = \widehat{P}^{r+d_c(\lambda^-)} v(\lambda_{(1)}) \cdot v(\lambda^-)$ .*

**Remark 5.6** Taking  $p = 2$  and  $P^r = Sq^r$ , this reduces to [16, Theorem 2.1], since that theorem can be applied to  $\lambda_{(1)} = (1^n)$  to obtain  $\widehat{Sq}^{r+d_c(\lambda^-)} v(\lambda_{(1)}) = [x_1^{2^{a_1}}, \dots, x_n^{2^{a_n}}]$ , where  $a_1 < \dots < a_n$ . The hypothesis on  $r$  is satisfied since  $r + d_c(\lambda^-) + n = r + d_c(\lambda) - d_c(\lambda^-) = 2^{a_1} + \dots + 2^{a_n}$ .

Combining Theorem 5.3 with Theorem 5.5, we obtain our main theorem.

**Theorem 5.7** Let  $\lambda$  be  $\mathbf{T}$ -regular with  $\mathbf{T}$ -conjugate  $\gamma$  of length  $m$ . For  $1 \leq k \leq m$ , let  $\gamma_k = (n_k - 1)(p - 1) + b_k$ , where  $n_k \geq 1$  and  $1 \leq b_k \leq p - 1$ . Then

$$\widehat{P}^{r_m} \dots \widehat{P}^{r_2} \widehat{P}^{r_1} v(\lambda) = w(\lambda'),$$

where  $r_k = (b_k + 1)p_{n_k-1} - (n_k - 1) - \sum_{j=k+1}^m p^{j-k-1} \gamma_j$ .

This theorem determines the first occurrence degree  $d_c(\lambda)$  when  $\lambda$  is  $\mathbf{T}$ -regular.

**Corollary 5.8** Let  $\lambda$  be  $\mathbf{T}$ -regular with  $\mathbf{T}$ -conjugate  $\gamma$ . Then the degree in which the irreducible module  $L(\lambda)$  first occurs as a composition factor in the polynomial algebra  $\mathbf{P}$  is given by

$$d_c(\lambda) = \sum_{i=1}^m p^{i-1} \gamma_i, \tag{9}$$

and the  $\mathbb{F}_p[M_n]$ -submodule of  $\mathbf{P}^{d_c(\lambda)}$  generated by  $v(\lambda)$  has a quotient module isomorphic to  $L(\lambda)$ .

**Proof** By [7] or [12]  $w(\lambda')$  generates a submodule of  $\mathbf{P}^{d_s(\lambda)}$  isomorphic to  $L(\lambda)$ . By Theorem 5.7, there is a Steenrod operation  $\theta = \theta(\lambda)$  and a polynomial  $v(\lambda) \in \mathbf{P}^d$ , where  $d$  is given by (9), such that  $\theta(v(\lambda)) = w(\lambda')$ . Hence the quotient of the submodule generated by  $v(\lambda)$  in  $\mathbf{P}^d$  by the intersection of this submodule with the kernel of  $\theta$  is a composition factor of  $\mathbf{P}^d$  which is isomorphic to  $L(\lambda)$ . Hence the first occurrence degree  $d_c(\lambda) \leq d$ . But  $d_c(\lambda) \geq d$  by [3, Proposition 2.13], and hence  $d_c(\lambda) = d$ .  $\square$

As an example, for  $p = 3$  the partition  $\lambda = (5, 3, 2)$  is  $\mathbf{T}$ -regular with  $\mathbf{T}$ -conjugate  $\gamma = (6, 3, 1)$ . The module  $L(5, 3, 2)$  first occurs as a composition factor in degree  $6 + 3 \cdot 3 + 1 \cdot 9 = 24$ , and as a submodule in degree  $5 + 3 \cdot 3 + 2 \cdot 9 = 32$ . The calculations of [1] and [6] for  $n \leq 3$  support the conjecture that the first occurrence degree  $d_c(\lambda)$  is given by the formula above if and only if  $\lambda$  is  $\mathbf{T}$ -regular.

The integers  $r_i$  in Theorem 5.7 can be calculated from a tableau  $\text{Tab}(\lambda)$  obtained by entering integers into the diagram of  $\lambda$  as follows: if a box in row  $i$  is the highest box in its antidiagonal, write  $p_{i-1}$  in that box and continue down the antidiagonal, multiplying the number entered at each step by  $p$ .

**Lemma 5.9** *The sum of the numbers entered in the  $k$ th block of  $p-1$  columns using the above rule is  $r_k$ . The element  $P^{r_1}P^{r_2}\dots P^{r_m}$  is an admissible monomial in  $\mathcal{A}_p$ , i.e.  $r_k \geq pr_{k+1}$  for  $1 \leq k \leq m-1$ .*

**Example 5.10** For  $p = 3$ ,  $\lambda = (6, 5, 4, 3, 2)$ , we obtain  $(r_1, r_2, r_3) = (100, 20, 1)$  using the tableau below.

$$\text{Tab}(\lambda) = \begin{array}{|c|c|c|c|c|c|} \hline 0 & 0 & 0 & 0 & 0 & 0 \\ \hline 0 & 0 & 0 & 0 & 1 & \\ \hline 0 & 0 & 3 & 4 & & \\ \hline 9 & 12 & 13 & & & \\ \hline 39 & 40 & & & & \\ \hline \end{array}$$

Noting that  $\widehat{P}^r = (-1)^r \chi(P^r)$ , in this case Theorem 5.7 states that in  $\mathbf{P}^{300}$ ,

$$\begin{aligned} \chi(P^{100}P^{20}P^1) & (x_1^2 \cdot [x_1, x_2^3]^2 \cdot [x_1, x_2^3, x_3^9]^2 \cdot [x_2, x_3^3, x_4^9] \cdot [x_3, x_4^3] \cdot [x_4, x_5^3] \cdot x_5) \\ & = -[x_1, x_2^3, x_3^9, x_4^{27}, x_5^{81}]^2 \cdot [x_1, x_2^3, x_3^9, x_4^{27}] \cdot [x_1, x_2^3, x_3^9] \cdot [x_1, x_2^3] \cdot x_1. \end{aligned}$$

**Proof of Lemma 5.9** The inequality  $r_k \geq pr_{k+1}$  for  $1 \leq k \leq m-1$  is clear from the algorithm, and can also be checked directly from the definition of  $r_k$ . Since  $r_2(\lambda) = r_1(\lambda^-)$ , and so on, we need only check the algorithm for  $r_1$ .

To do this, we introduce a second tableau by entering  $p_{i-1}$  in the  $i$ th row of the first block of  $p-1$  columns and  $-p^{j-2}$  in all the boxes in the  $j$ th block of  $p-1$  columns for  $j > 1$ . In Example 5.10 this is as follows.

$$\begin{array}{|c|c|c|c|c|c|} \hline 0 & 0 & -1 & -1 & -3 & -3 \\ \hline 1 & 1 & -1 & -1 & -3 & \\ \hline 4 & 4 & -1 & -1 & & \\ \hline 13 & 13 & -1 & & & \\ \hline 40 & 40 & & & & \\ \hline \end{array}$$

The entries in a antidiagonal running from the  $(i, j)$  box for  $1 \leq j \leq p-1$  are then  $p_{i-1}, -1, -p, \dots, -p^{s-2}$ , and their sum  $p_{i-1} - p_{s-1} = p^{s-1}p_{i-s}$  is the number entered in this box in  $\text{Tab}(\lambda)$ .

It remains to check that the sum of all the entries in the second tableau is  $r_1 = (b_1 + 1)p_{n-1} - (n-1) - d_c(\lambda^-)$ . To see this, note that the entries in  $\lambda^-$  sum to  $-d_c(\lambda^-)$ , while the entries in the last row of  $\lambda_{(1)}$  sum to  $bp_{n-1}$  and the entries in the first  $n-1$  rows sum to  $(p-1)(p_0 + p_1 + \dots + p_{n-2}) = p_{n-1} - (n-1)$ .  $\square$

Since  $w(n)$  is a product of linear factors, so also is  $v(\lambda)$ , and by Theorems 5.3 and 5.5 so also is  $\widehat{P}^{r_1}v(\lambda)$ . The following calculation shows that  $v(\lambda)$  divides  $\widehat{P}^{r_1}v(\lambda)$ , and that the quotient can be read off from  $\text{Tab}(\lambda)$  as follows: replace the entry  $p_{i-1} - p_{s-1}$  in the  $(i, j)$  box,  $1 \leq j \leq p - 1$ , by the product of all linear polynomials of the form  $x_i + \sum_{k < i} c_k x_k$ , excluding those where  $c_k = 0$  for  $1 \leq k \leq i - s$ .

**Corollary 5.11** *Let  $\lambda$  be a  $\mathbf{T}$ -regular partition. Let the  $k$ th antidiagonal in the diagram of  $\lambda$  have length  $s_k$  and lowest box in row  $n_k$ . Then*

$$\frac{\widehat{P}^{r_1}v(\lambda)}{v(\lambda)} = \prod_{k=1}^{\gamma_1} \prod_{\mathbf{c}} (c_1 x_1 + \dots + c_{n_k-1} x_{n_k-1} + x_{n_k}),$$

where the inner product is over all vectors  $\mathbf{c} = (c_1, \dots, c_{n_k-1}) \in \mathbb{F}_p^{n_k-1}$  such that  $(c_1, \dots, c_{n_k-s_k}) \neq (0, \dots, 0)$ .

In Theorem 1.1,  $\lambda = ((p - 1)^n)$ ,  $v(\lambda) = (x_1 x_2 \dots x_n)^{p-1}$  and  $\widehat{P}^{r_1}v(\lambda) = [x_1, x_2^p, \dots, x_n^{p^{n-1}}]^{p-1}$ . Since  $s_k = 1$  for  $1 \leq k \leq n(p - 1)$ , the quotient is the product of all linear polynomials in  $x_1, \dots, x_n$  which are not monomials.

**Proof of Corollary 5.11** The proof is by induction on the number of antidiagonals  $\gamma_1$ . Let  $\phi(\lambda) = \widehat{P}^{r_1}v(\lambda)/v(\lambda)$ , where  $r_1 = r_1(\lambda)$ . Let  $s$  denote the length of the last antidiagonal in the diagram of  $\lambda$ , and let  $\mu$  be the  $\mathbf{T}$ -regular partition obtained by removing this antidiagonal from the diagram of  $\lambda$ . Then by Theorems 5.3 and 5.5,

$$\frac{\phi(\lambda)}{\phi(\mu)} = \frac{[x_1, x_2^p, \dots, x_n^{p^{n-1}}]}{[x_1, x_2^p, \dots, x_{n-1}^{p^{n-2}}]} \cdot \frac{v(\lambda^-)}{v(\mu^-)} \cdot \frac{v(\mu)}{v(\lambda)}.$$

Note that  $\lambda^- = \mu^-$  when  $s = 1$ . Now  $[x_1, x_2^p, \dots, x_n^{p^{n-1}}]/[x_1, x_2^p, \dots, x_{n-1}^{p^{n-2}}] = \prod_{\mathbf{c}} (c_1 x_1 + \dots + c_{n-1} x_{n-1} + x_n)$ , where the product is taken over all vectors  $\mathbf{c} = (c_1, \dots, c_{n-1}) \in \mathbb{F}_p^{n-1}$ . Also  $v(\lambda)/v(\mu) = v_{\gamma_1}(\lambda) = [x_{n-s+1}, x_{n-s+2}^p, \dots, x_n^{p^{s-1}}]$ . Similarly  $v(\lambda^-)/v(\mu^-) = [x_{n-s+1}, x_{n-s+2}^p, \dots, x_{n-1}^{p^{s-2}}]$ . The quotient of these determinants is the product of all  $p^{s-1}$  linear polynomials  $c_{n-s+1} x_{n-s+1} + \dots + c_{n-1} x_{n-1} + x_n$ , so  $\phi(\lambda)/\phi(\mu) = \prod_{\mathbf{c}} (c_1 x_1 + \dots + c_{n-1} x_{n-1} + x_n)$ , where the product is over all  $\mathbf{c} = (c_1, \dots, c_{n-1}) \in \mathbb{F}_p^{n-1}$  with  $c_i \neq 0$  for some  $i$  such that  $1 \leq i \leq n - s$ .

## 6 Proof of the linking theorem

In this section we prove Theorems 5.5 and 5.7. The following lemma will help in checking conditions on the numerical function  $\alpha$ .

**Lemma 6.1** (i) *Let  $R \geq 1$  have base  $p$  expansion  $R = j_1p^{a_1} + \dots + j_t p^{a_t}$ , where  $1 \leq j_1, \dots, j_t \leq p - 1$ ,  $0 \leq a_1 < \dots < a_t$ , and let  $k \geq 0$ . Then  $\alpha(R - p^k) \geq \alpha(R) - 1$ , with equality if and only if  $k = a_i$ ,  $1 \leq i \leq t$ .*

(ii) *With notation as in Theorem 5.5, and with  $\mu$  and  $s$  as in the proof of Corollary 5.11, for  $r \geq 1$  and  $k \geq 0$  we have*

$$R(r - p_k + p_{s-1}, \mu) = R(r - p_k + d_c(\lambda^-), \mu_{(1)}) = R(r, \lambda) - p^k.$$

**Proof** If  $k \neq a_i$  for  $1 \leq i \leq t$ , then subtraction of  $p^k$  must yield at least one new term  $(p - 1)p^a$  in the base  $p$  expansion. This proves (i). For (ii), since  $d_c(\lambda) = d_c(\lambda_{(1)}) + p d_c(\lambda^-)$  and  $d_c(\lambda_{(1)}) = \gamma_1$  we have  $R = R(r, \lambda) = (p - 1)(r + d_c(\lambda^-)) + \gamma_1$ . Comparing the first occurrence degrees for  $L(\lambda)$  and  $L(\mu)$  given by (9),

$$d_c(\lambda) = d_c(\mu) + p_s, \quad d_c(\lambda^-) = d_c(\mu^-) + p_{s-1}, \quad d_c(\lambda_{(1)}) = d_c(\mu_{(1)}) + 1. \tag{10}$$

Hence we have  $R(r - p_k + p_{s-1}, \mu) = (p - 1)(r - p_k + p_{s-1} + d_c(\mu^-)) + d_c(\mu_{(1)}) = (p - 1)(r - p_k + d_c(\lambda^-)) + d_c(\mu_{(1)}) = R(r - p_k + d_c(\lambda^-), \mu_{(1)}) = R - (p - 1)p_k - 1 = R - p^k$ . □

**Proof of Theorem 5.5(i)** We argue by induction on  $\gamma_1$ , the number of antidiagonals of  $\lambda$ . With  $\mu$  and  $s$  as above,  $v(\lambda) = [x_{n-s+1}, x_{n-s+2}^p, \dots, x_n^{p^{s-1}}] \cdot v(\mu)$ . Using formula (4) and Lemma 2.2, for all  $r \geq 1$  we have

$$\widehat{P}^r v(\lambda) = \sum_{k \geq s-1} [x_{n-s+1}, x_{n-s+2}^p, \dots, x_{n-1}^{p^{s-2}}, x_n^{p^k}] \cdot \widehat{P}^{r-p_k+p_{s-1}} v(\mu). \tag{11}$$

By Lemma 6.1, if  $\alpha(R(r, \lambda)) > \gamma_1$  then  $\alpha(R(r - p_k + p_{s-1}, \mu)) > \gamma_1 - 1$  for all  $k \geq 0$ . Since  $\mu$  has  $\gamma_1 - 1$  antidiagonals, the second factor in each term of (11) is zero by the induction hypothesis. Hence  $\widehat{P}^r v(\lambda) = 0$  if  $\alpha(R(r, \lambda)) > \gamma_1$ , completing the induction.

**Proof of Theorem 5.5(ii)** As in Lemma 6.1, let  $R = R(r, \lambda)$  have base  $p$  expansion  $R = j_1p^{a_1} + \dots + j_t p^{a_t}$ , let  $\alpha(R) = \gamma_1$  and let  $R' = R(r - p_k + p_{s-1}, \mu)$ . Then the lemma gives  $\alpha(R') = \gamma_1 - 1$  if  $k = a_i$ ,  $1 \leq i \leq t$ , and  $\alpha(R') > \gamma_1 - 1$  otherwise. Hence, applying part (i) of the theorem to (11), we have

$$\widehat{P}^r v(\lambda) = \sum_{i=1}^t [x_{n-s+1}, x_{n-s+2}^p, \dots, x_{n-1}^{p^{s-2}}, x_n^{p^{a_i}}] \cdot \widehat{P}^{r-p_{a_i}+p_{s-1}} v(\mu).$$

Since  $\alpha(R(r - p_{a_i} + p_{s-1}, \mu) = \gamma_1 - 1 = d_c(\mu_{(1)})$  by the lemma, and  $p_{s-1} + d_c(\mu^-) = d_c(\lambda^-)$ , the inductive hypothesis on  $\mu$  gives

$$\widehat{P}^{r-p_{a_i}+p_{s-1}}v(\mu) = \widehat{P}^{r-p_{a_i}+d_c(\lambda^-)}v(\mu_{(1)}) \cdot v(\mu^-), \quad 1 \leq i \leq t.$$

We can similarly use the lemma to simplify the right hand side of the required identity. Since  $v(\lambda_{(1)}) = x_n v(\mu_{(1)})$ , from (4) and (2) we have

$$\widehat{P}^{r+d_c(\lambda^-)}v(\lambda_{(1)}) = \sum_{k \geq 0} x_n^{p^k} \widehat{P}^{r+d_c(\lambda^-)-p^k}v(\mu_{(1)}).$$

By the lemma,  $R(r + d_c(\lambda^-) - p^k, \mu_{(1)}) = R - p^k$ , so that by (i) we can again reduce to the sum over  $k = a_i, 1 \leq i \leq t$ . As  $v(\lambda^-) = [x_{n-s+1}, x_{n-s+2}^p, \dots, x_{n-1}^{p^{s-2}}] \cdot v(\mu^-)$ , it remains after cancelling the factor  $v(\mu^-)$  and rearranging terms to prove that

$$\sum_{i=1}^t \left( [x_{n-s+1}, x_{n-s+2}^p, \dots, x_{n-1}^{p^{s-2}}, x_n^{p^{a_i}}] - [x_{n-s+1}, x_{n-s+2}^p, \dots, x_{n-1}^{p^{s-2}}] x_n^{p^{a_i}} \right) \cdot f_i = 0,$$

where  $f_i = \widehat{P}^{r-p_{a_i}+d_c(\lambda^-)}v(\mu_{(1)})$ . The expansion of the  $s \times s$  determinant in the  $p^{a_i}$  powers of the variables is

$$\sum_{j=1}^s (-1)^{s-j} [x_{n-s+1}, \dots, x_{n-s+j-1}^{p^{j-2}}, x_{n-s+j+1}^{p^{j-1}}, \dots, x_n^{p^{s-2}}] x_n^{p^{a_i}}$$

Thus the term with  $j = s$  cancels, and interchanging the  $i$  and  $j$  summations, the required formula becomes

$$\sum_{j=1}^{s-1} (-1)^{s-j} [x_{n-s+1}, \dots, x_{n-s+j-1}^{p^{j-2}}, x_{n-s+j+1}^{p^{j-1}}, \dots, x_n^{p^{s-2}}] \cdot \sum_{i=1}^t x_n^{p^{a_i}} f_i = 0.$$

Since  $\widehat{P}^{r+d_c(\lambda^-)}(x_{n-s+j} v(\mu_{(1)})) = \sum_{i=1}^t x_n^{p^{a_i}} f_i$  by a similar argument using (4), (1) and Lemma 6.1, it suffices to prove that the monomial  $x_{n-s+j} v(\mu_{(1)})$  is in the kernel of  $\widehat{P}^{r+d_c(\lambda^-)}$  for  $1 \leq j \leq s - 1$ . This monomial is divisible by  $x_{n-s+j}^p$ . By permuting the variables, it suffices to consider the case where it is divisible by  $x_1^p$ . Hence the proof of Theorem 5.5 is completed by the following calculation.

**Proposition 6.2** *Let  $R = R(r, \lambda)$  and let  $\alpha(R) = \gamma_1$ , where  $\gamma_1 = (n - 1)(p - 1) + b$  and  $1 \leq b \leq p - 1$ . Then*

$$\widehat{P}^{r+d_c(\lambda^-)}(x_1^p (x_2 \cdots x_{n-1})^{p-1} \cdot x_n^{b-1}) = 0.$$

**Proof** By Lemma 2.3, with  $f = x_1$  and  $g = (x_2 \cdots x_{n-1})^{p-1} \cdot x_n^{b-1}$ ,

$$\widehat{P}^u(x_1^p \cdot g) = \sum_{u=pv+w} (\widehat{P}^v x_1)^p \cdot \widehat{P}^w(g).$$

Note that  $g = v(\nu)$  where  $\nu = ((p-1)^{n-2}(b-1))$ . By (2),  $\widehat{P}^v x_1 = 0$  for  $v \neq p_k, k \geq 0$ , so we may assume that  $w = u - pv = r + d_c(\lambda^-) - p \cdot p_k$ . Since  $p \cdot p_k = p_{k+1} - 1$  and  $d_c(\mu_{(1)}) = p - 1 + d_c(\nu)$ ,  $R(w, \nu) = R(r - p_{k+1} + d_c(\lambda^-), \mu_{(1)}) = R - p^{k+1}$  by Lemma 6.1(ii). Since  $\alpha(R) = \gamma_1$ , Lemma 6.1(i) gives  $\alpha(R(w, \nu)) \geq \gamma_1 - 1 > \gamma_1 - p$ . Since  $d_c(\nu) = \gamma_1 - p$ ,  $\widehat{P}^w g = 0$  by Theorem 5.5(i).  $\square$

**Proof of Theorem 5.7** This follows from Theorem 5.5 by induction on  $m$ . Let  $\gamma_1 = (n-1)(p-1) + b, 1 \leq b \leq p-1$ . We wish to apply Theorem 5.5 with  $r = r_1$ , so we must check that  $\alpha(R(r_1, \lambda)) = \gamma_1$ . For this, note that (9) gives  $d_c(\lambda^-) = \sum_{j=2}^m p^{j-2} \gamma_j$ , so that  $r_1 + d_c(\lambda^-) = (b+1)p_{n-1} - (n-1)$ . Thus  $R(r_1, \lambda) = (p-1)(r_1 + d_c(\lambda^-)) + \gamma_1 = (b+1)(p^{n-1} - 1) - (p-1)(n-1) + \gamma_1 = bp^{n-1} + (p^{n-1} - 1)$ . Hence  $r_1$  satisfies the hypothesis of Theorem 5.5, so that  $\widehat{P}^{r_1} v(\lambda) = \widehat{P}^{r_1 + d_c(\lambda^-)} v(\lambda_{(1)}) \cdot v(\lambda^-)$ . By Theorem 5.3,  $\widehat{P}^{r_1 + d_c(\lambda^-)} v(\lambda_{(1)}) = w(\lambda'_{(1)})$ .

Now  $r_i(\lambda) = r_{i-1}(\lambda^-)$  for  $2 \leq i \leq m$ , and so the inductive step reduces to showing that

$$\widehat{P}^{r_m} \cdots \widehat{P}^{r_2} \left( w(\lambda'_{(1)}) \cdot v(\lambda^-) \right) = w(\lambda'_{(1)}) \cdot \widehat{P}^{r_m} \cdots \widehat{P}^{r_2} v(\lambda^-). \tag{12}$$

Recall from Lemma 5.9 that  $r_1, \dots, r_m$  is an admissible sequence, i.e.  $r_k \geq pr_{k+1}$  for  $k \geq 1$ . Since  $r_1 \leq (b+1)p_{n-1}, r_1 < p^{n-1}$  if  $b < p-1$  and  $r_1 < p^n$  if  $b = p-1$ . Thus we can deduce (12) from Lemma 2.2 and the coproduct formula (4), as follows. We have  $w(\lambda'_{(1)}) = w(n)^b w(n-1)^{p-1-b}$ . Now  $\widehat{P}^r w(n) = 0$  for  $0 < r < p^{n-1}$  and  $\widehat{P}^r w(n-1) = 0$  for  $0 < r < p^{n-2}$ . If there are any factors  $w(n-1)$  in  $w(\lambda'_{(1)})$ , then  $r_2 < p^{n-2}$ , and otherwise it suffices to have  $r_2 < p^{n-1}$ .

## 7 First occurrence submodules

For a  $\mathbf{T}$ -regular partition  $\lambda$ , the  $\mathbb{F}_p[M_n]$ -submodule of  $\mathbf{P}^{d_c(\lambda)}$  generated by the first occurrence polynomial  $v(\lambda)$  is a ‘representative polynomial’ for  $L(\lambda)$  in the sense that this module has a quotient isomorphic to  $L(\lambda)$  (see Corollary 5.8). In the case where  $\lambda = (p-1)\kappa$  for a column 2-regular partition  $\kappa$ , the leading monomial  $s(\lambda) = x_1^{p^{\kappa_1}-1} \cdots x_n^{p^{\kappa_n}-1}$  has the same property. This is implicit in

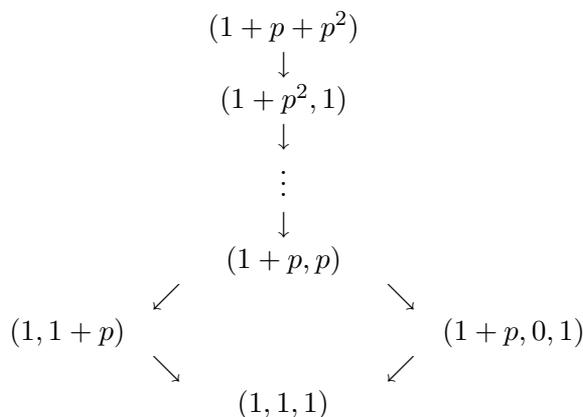

the work of Carlisle and Kuhn [2], who identify a subquotient  $\mathbf{T}^\gamma$  of  $\mathbf{P}^{d_c(\lambda)}$  such that  $\mathbf{T}^\gamma \cong \mathbf{T}^{\gamma_1} \otimes \dots \otimes \mathbf{T}^{\gamma_m}$ , where  $\gamma$  is the  $\mathbf{T}$ -conjugate of  $\lambda$ . Explicitly, if  $v_i \in \mathbf{T}^{\gamma_i}$  corresponds to a monomial in  $x_1, \dots, x_n$  with all exponents  $< p$ , then  $v_1 \otimes \dots \otimes v_m \in \mathbf{T}^{\gamma_1} \otimes \dots \otimes \mathbf{T}^{\gamma_m}$  corresponds to the equivalence class of  $v_1 \cdot v_2^p \cdots v_m^{p^{m-1}}$  in the appropriate subquotient of  $\mathbf{P}^{d_c(\lambda)}$ . Proposition 5.4(ii) shows that, taking  $v_j = v(\lambda_{(j)})$ , this monomial is  $s(\lambda)$ . Tri [14] has recently proved that if  $\lambda$  is  $\mathbf{T}$ -regular, then  $L(\lambda)$  is a composition factor in  $\mathbf{T}^\gamma$ .

We recall from [16, Section 4] the notion of a *base  $p$   $\omega$ -vector*.

**Definition 7.1** Given a prime  $p$ , the *base  $p$   $\omega$ -vector*  $\omega(s)$  of a sequence of non-negative integers  $s = (s_1, \dots, s_n)$  is defined as follows. Write each  $s_i$  in base  $p$  as  $s_i = \sum_{j \geq 1} s_{i,j} p^{j-1}$ , where  $0 \leq s_{i,j} \leq p - 1$ , and let  $\omega_j(s) = \sum_{i=1}^n s_{i,j}$ , i.e. add the base  $p$  expansions without ‘carries’. Then  $\omega(s) = (\omega_1(s), \dots, \omega_l(s))$ , with *length*  $l = \max\{j : \omega_j(s) > 0\}$  and *degree*  $d = \sum_{i=1}^n s_i = \sum_{j=1}^l \omega_j(s) p^{j-1}$ .

Given  $\omega$ -vectors  $\rho$  and  $\sigma$ , we say that  $\rho$  *dominates*  $\sigma$ , and write  $\rho \succeq \sigma$  or  $\sigma \preceq \rho$ , if and only if  $\sum_{i=1}^k p^{i-1} \rho_i \geq \sum_{i=1}^k p^{i-1} \sigma_i$  for all  $k \geq 1$ . By the  $\omega$ -vector of a monomial  $\prod_{i=1}^n x_i^{s_i}$  we mean the  $\omega$ -vector of its sequence of exponents  $s = (s_1, \dots, s_n)$ . The dominance order on  $\omega$ -vectors of the same degree is compatible with left lexicographic order.

**Example 7.2** The lattice of base  $p$   $\omega$ -vectors of degree  $1 + p + p^2$  is shown below.

**Proposition 7.3** Let  $\lambda$  be a  $\mathbf{T}$ -regular partition. Then the  $\omega$ -vector of the spike monomial  $s(\lambda)$  is the partition  $\gamma$   $\mathbf{T}$ -conjugate to  $\lambda$ , and the polynomial  $v(\lambda)$  is the sum of  $(-1)^{\epsilon(\lambda)} s(\lambda)$  and monomials  $f$  such that  $\omega(f) \prec \gamma$ .

**Proof** The proof is the same as that given in [16, proposition 4.5], with 2 replaced by  $p$  and  $\lambda'$  replaced by  $\gamma$ . For  $\epsilon(\lambda)$ , see Proposition 5.4(iii).  $\square$

Corollary 5.8 and Proposition 7.3 together provide a ‘topological’ proof that the  $\mathbb{F}_p[M_n]$ -submodule of  $\mathbf{P}^{d_c(\lambda)}$  generated by  $s(\lambda)$  has a quotient module isomorphic to  $L(\lambda)$ . The next result provides a further comparison between the spike monomial  $s(\lambda)$  and the polynomial  $v(\lambda)$  in a special case. We conjecture that the corresponding statement holds for all  $\mathbf{T}$ -regular partitions  $\lambda$ .

**Proposition 7.4** *Assume that  $\lambda_i = (p - 1)\kappa_i$  for  $1 \leq i \leq n$ , where  $\kappa = (\kappa_1, \dots, \kappa_n)$  is a column 2-regular partition. Then the submodule of  $\mathbf{P}^{d_c(\lambda)}$  generated by the polynomial  $v(\lambda)$  is contained in the submodule generated by the spike monomial  $s(\lambda)$ .*

The proof requires a preliminary lemma.

**Lemma 7.5** *If  $f \in \mathbb{F}_p[x_2, \dots, x_n]$  and  $1 \leq s \leq n$ , then the  $\mathbb{F}_p[M_n]$ -submodule of  $\mathbf{P}$  generated by  $x_1^{p^s-1} \cdot f$  contains  $[x_1, x_2^p, \dots, x_s^{p^s-1}]^{p-1} \cdot f$ .*

**Proof** For each linear form  $v = a_1x_1 + \dots + a_sx_s$ , where  $a_i \in \mathbb{F}_p$  for  $1 \leq i \leq s$ , let  $t_v : \mathbf{P} \rightarrow \mathbf{P}$  be the transvection mapping  $x_1$  to  $v$  and fixing  $x_2, \dots, x_n$ . We claim that the following equation holds in  $\mathbb{F}_p[x_1, \dots, x_s]$ .

$$(-1)^s [x_1, x_2^p, \dots, x_s^{p^s-1}]^{p-1} = \sum_v v^{p^s-1}. \tag{13}$$

Since  $t_v$  does not change the variables  $x_2, \dots, x_n$  which can occur in  $f$ , it follows from (13) that  $\sum_v t_v$  is an element of the semigroup algebra  $\mathbb{F}_p[M_n]$  which maps  $x_1^{p^s-1} \cdot f$  to  $(-1)^s [x_1, x_2^p, \dots, x_s^{p^s-1}]^{p-1} \cdot f$ .

To prove (13), first note that the right hand side is  $GL_s(\mathbb{F}_p)$ -invariant. Further, it is mapped to 0 by every singular matrix  $g \in M_s$ , since vectors  $(a_1, \dots, a_s)$  and  $(a'_1, \dots, a'_s)$  in  $\mathbb{F}_p^s$  in the same coset of the kernel of  $g$  yield terms in (13) with the same image under  $g$ , and  $p$  divides the order of this coset. Arguing as in the first or second proof of Theorem 1.1, with  $s$  in place of  $n$ , it follows that (13) holds up to a (possibly zero) scalar.

Finally we verify that the monomial  $m = x_1^{p-1}x_2^{p(p-1)} \dots x_s^{p^{s-1}(p-1)}$  has coefficient  $(-1)^s$  in the right hand side of (13). For each linear form  $v$ , we have  $v^{p^s-1} = v^{p^{s-1}(p-1)} \dots v^{p(p-1)} \cdot v^{p-1}$ , where  $v^{p^j(p-1)} = (a_1x_1^{p^j} + \dots + a_sx_s^{p^j})^{p-1}$  for  $0 \leq j \leq s - 1$ . The exponent  $p - 1$  in  $m$  must come from the last factor in this

product, so we must choose the term  $(a_1x_1)^{p-1} = x_1^{p-1}$  from the last factor, and  $a_1 \neq 0$ . In the same way, we must choose the term  $(a_2x_2^p)^{p-1} = x_2^{p(p-1)}$  from the last but one factor, and  $a_2 \neq 0$ . Continuing in this way, we see that each of the  $(p-1)^s$  linear forms  $v$  with all coefficients  $a_i \neq 0$  gives a term containing  $m$  (with coefficient 1), while other choices of  $v$  give terms not containing  $m$ . Thus the scalar coefficient in (13) is  $(-1)^s$ .  $\square$

The following example shows how to apply Lemma 7.5 to a partition  $\lambda$  of the form  $(p-1)\kappa$ , so as to generate  $v(\lambda)$  from  $s(\lambda)$ .

**Example 7.6** Let  $p = 3$  and let  $\lambda = (6, 6, 4, 4, 2)$ , so that  $s(\lambda) = x^{26}y^{26}z^8t^8u^2$  and  $v(\lambda) = x^2[x, y^3]^2[x, y^3, z^9]^2[y, z^3, t^9]^2[t, u^3]^2$ .

Begin by permuting the variables, so as to work with the spike  $u^8t^{26}z^{26}y^8x^2$ . Apply Lemma 7.5 with  $x_1 = y$  and  $s = 2$  to generate  $[y, x^3]^2 \cdot u^8t^{26}z^{26}x^2$ . Repeat with  $x_1 = z$  and  $s = 3$  to generate  $[z, y^3, x^9]^2 \cdot u^8t^{26}[y, x^3]^2x^2$ , then with  $x_1 = t$  and  $s = 3$  to generate  $[t, z^3, y^9]^2 \cdot u^8[z, y^3, x^9]^2[y, x^3]^2x^2$ , and finally with  $x_1 = u$  and  $s = 2$  to generate  $v(\lambda)$ .

**Proof of Proposition 7.4** We first observe (see [16, Proposition 4.9]) that the (multi)set of lengths of the antidiagonals of the column 2-regular partition  $\kappa$  is equal to the (multi)set of lengths of the rows. Hence the spike monomial  $\tilde{s}(\lambda) = x_n^{p^{s_n}-1}x_{n-1}^{p^{s_{n-1}}-1} \cdots x_1^{p^{s_1}-1}$ , where  $s_k$  is the length of the  $k$ th antidiagonal of the diagram of  $\kappa$ , can be obtained from  $s(\lambda)$  by a suitable permutation of the variables. We can now obtain  $v(\lambda)$  from  $\tilde{s}(\lambda)$  by  $n-1$  successive applications of Lemma 7.5, following the method illustrated by Example 7.6.

## 8 T-regular partitions and the Milnor basis

In this section we link the first occurrence polynomial  $v(\lambda)$  and its leading monomial  $s(\lambda)$  to the polynomial  $p(\lambda') = \prod_{j=1}^m w(\lambda'_{(j)})^{p^j-1}$ , which generates a submodule occurrence of  $L(\lambda)$  in a higher degree. Here, as in Proposition 5.4,  $\lambda_{(j)}$  is the partition given by the  $j$ th block of  $p-1$  columns in the diagram of the **T**-regular partition  $\lambda$ , and  $m$  is the length of  $\gamma$ , the **T**-conjugate of  $\lambda$ . In the case  $\lambda = (p-1)\kappa$ , we also link the first submodule occurrence polynomial  $w(\lambda')$  to  $p(\lambda')$ . The linking is achieved by Milnor basis elements in  $\mathcal{A}_p$  which are combinatorially related to  $\lambda$ . We also obtain a relation between monomials in **P** and Milnor basis elements in terms of  $\omega$ -vectors. These results extend some of the results of [16, Section 5].

As in Proposition 5.4, let  $\lambda_i = a_i(p - 1) + b_i$ , where  $a_i \geq 0$ ,  $1 \leq b_i \leq p - 1$ . Following [16], for  $R = ((b_1 + 1)p^{a_1} - 1, \dots, (b_n + 1)p^{a_n} - 1)$  we call the Milnor basis element  $P(R)$  the *Milnor spike* associated to  $\lambda$ . We note that  $\omega(R) = \gamma$ . A Milnor spike is an admissible monomial [4]. For example, if  $p = 3$  and  $\lambda = (4, 3, 1)$  then the corresponding Milnor spike is  $P(8, 5, 1) = P^{32}P^8P^1$ , and for the  $\mathbf{T}$ -conjugate partition  $\gamma = (5, 3)$  it is  $P(17, 5) = P^{32}P^5$ . In this example,  $\lambda'_{(1)} = (3, 2)$  and  $\lambda'_{(2)} = (2, 1)$ , so that  $p(\lambda') = w(3)w(2) \cdot (w(2)w(1))^3 = [x_1, x_2^3, x_3^9] \cdot [x_1, x_2^3]^4 \cdot x_1^3$ .

**Theorem 8.1** *Let  $\lambda$  be  $\mathbf{T}$ -regular with  $\mathbf{T}$ -conjugate  $\gamma$ .*

- (i)  $P(R)s(\lambda) = (-1)^{\epsilon(\lambda)}P(R)v(\lambda) = p(\lambda')$ , where  $P(R)$  is the Milnor spike associated to  $(\lambda_2, \dots, \lambda_n)$ .
- (ii) If  $\lambda = (p - 1)\kappa$ , where  $\kappa$  is column 2-regular,  $P(S)w(\lambda') = p(\lambda')$ , where  $P(S)$  is the Milnor spike associated to  $(\gamma_2, \dots, \gamma_m)$ .
- (iii) There are formulae corresponding to (i) and (ii) for the Milnor spikes associated to  $\lambda$  and  $\gamma$ , with  $p(\lambda')$  replaced by  $p(\lambda')^p$ .

**Remark 8.2** (iii) follows immediately from (i) and (ii) for degree reasons. The omission of the first terms in  $R$  and  $S$  corresponds to omitting the highest Steenrod power  $P^d$  in the admissible monomial forms of  $P(R)$  and  $P(S)$ . In fact  $d = \deg p(\lambda')$ , so that  $P^d p(\lambda') = p(\lambda')^p$ . In the example  $p = 3$ ,  $\lambda = (4, 3, 1)$  above, (i) states that  $P^8P^1(x_1^8x_2^5x_3) = -P^8P^1(x_1^2 \cdot [x_1, x_2^3]^2 \cdot [x_2, x_3^3]) = [x_1, x_2^3, x_3^9] \cdot [x_1, x_2^3]^4 \cdot x_1^3$ . The case  $\lambda = (4, 3, 1)$  is excluded from (ii), but in fact  $P^5w(\lambda') = -p(\lambda')$ . We believe that (ii) holds, up to sign, for all  $\mathbf{T}$ -regular  $\lambda$ .

We begin by proving the equivalence of the two statements in (i). For this we use the following generalization of [16, Theorem 5.9(i)]. The proof is based on Lemma 2.8, and follows that given in [16].

**Theorem 8.3** *Let  $R = (r_1, \dots, r_t)$  and let  $\omega(R) = \rho$ . If the  $\omega$ -vector  $\sigma$  of  $x_1^{s_1} \dots x_n^{s_n}$  does not dominate  $\rho$ , then  $P(R)(x_1^{s_1} \dots x_n^{s_n}) = 0$ . □*

**Proof of Theorem 8.1(i)** By Proposition 7.3, if the monomial  $f$  occurs in  $v(\lambda)$  and  $f \neq s(\lambda)$ , then  $\omega(f) \prec \gamma$ . If  $R = (r_1, \dots, r_n)$  where  $r_i = (b_i + 1)p^{a_i} - 1$ , so that  $P(R)$  is the Milnor spike associated to  $\lambda$ , then, as noted above,  $\omega(R) = \gamma$ . Hence, by Theorem 8.3,  $P(R)$  takes the same value on  $v(\lambda)$  and on its leading term  $(-1)^{\epsilon(\lambda)}s(\lambda)$ .

We evaluate  $P(R)s(\lambda)$  by induction on the length  $m$  of  $\gamma$ . The base case  $m = 1$  holds by our previous results, as follows. In this case,  $\lambda = (p - 1, \dots, p - 1, b)$ ,

with  $1 \leq b \leq p - 1$ , and has length  $n$ , while (i) states that  $P(R)s(\lambda) = w(\lambda')$ , where  $R = (p - 1, \dots, p - 1, b)$  has length  $n - 1$ . By Proposition 3.2(ii),  $P(R)g = \widehat{P}^{(b+1)p_{n-1}-(n-1)}g$  when  $\deg g \leq (n - 1)(p - 1) + b$ , and we may choose  $g = s(\lambda)$ . Hence the result follows from Theorem 5.3.

For the inductive step, we use Proposition 5.4(ii) to write  $s(\lambda) = f^p \cdot g$ , where  $g = v(\lambda_{(1)})$  and  $f = s(\lambda^-)$ . Hence  $P(R)s(\lambda) = \sum (P(S)f)^p \cdot P(T)g$  by Lemma 2.8, where the sum is over sequences  $S = (s_2, \dots, s_n)$ ,  $T = (t_2, \dots, t_n)$  such that  $r_i = ps_i + t_i$  for  $2 \leq i \leq n$ . Thus  $t_n = b_1$ ,  $s_n = 0$  and  $t_i \geq p - 1$  for  $2 \leq i \leq n - 1$ . If  $t_i \neq p - 1$  for some  $i < n$ , then  $P(T)$  has excess  $\sum_i t_i > \deg v(\lambda_{(1)}) = \gamma_1$ , so that  $P(T)(v(\lambda_{(1)})) = 0$ . Hence we may assume that  $T = (p - 1, \dots, p - 1, b_1)$ , so that  $s_i = (b_i + 1)p^{a_i - 1} - 1$  for  $2 \leq i \leq n - 1$ . By the argument for the case  $m = 1$ ,  $P(T)(v(\lambda_{(1)})) = w(\lambda'_{(1)})$ , and by the induction hypothesis applied to  $\lambda^-$ ,  $P(S)s(\lambda^-) = p(\lambda^-)$ . Since  $p(\lambda) = w(\lambda'_{(1)}) \cdot p(\lambda^-)^p$ , the induction is complete.  $\square$

**Proof of Theorem 8.1(ii)** Let  $\lambda = (p - 1)\kappa$ , where  $\kappa$  is column 2-regular. Then  $\gamma = (p - 1)\kappa'$  has length  $m = \kappa_1$ , and  $\lambda_{(i)} = ((p - 1)^{\kappa'_i})$ , so that  $w(\lambda_{(i)}) = w(\kappa'_i)^{p-1}$ . Also  $S = (p^{\kappa'_2} - 1, \dots, p^{\kappa'_m} - 1)$ , so that  $P(S) = P^{t_2} \dots P^{t_m}$ , where  $t_m = p^{\kappa'_m} - 1$  and  $t_i = pt_{i+1} + p^{\kappa'_i} - 1$  for  $1 \leq i < m$ . We shall argue by induction on  $m$ , the case  $m = 1$ , where  $P(S) = 1$ , being trivial. For  $2 \leq i \leq m$ , let

$$W_i(\lambda') = w(\lambda'_{(1)}) \cdots w(\lambda'_{(i)}) \cdot w(\lambda'_{(i+1)})^p \cdots w(\lambda'_{(m)})^{p^{m-i}},$$

so that  $W_1(\lambda') = p(\lambda')$  and  $W_m(\lambda') = w(\lambda')$ . We assume as inductive hypothesis on  $j$  that  $P^{t_j}W_j(\lambda') = W_{j-1}(\lambda')$  for  $j > i$ , and prove this for  $j = i$ .

It follows from Lemma 2.1 that  $P^r(w(n)^{p^i}) = 0$  unless  $r = p^i(p_n - p_j)$ , where  $0 \leq j \leq n$ . The largest of these values, equal to the degree of  $w(n)^{p^i}$ , is  $p^i \cdot p_n$ . Since  $w(\lambda'_{(i)})$  has degree  $p^{\kappa'_i} - 1$ , it follows by (downward) induction on  $i$  that  $t_i$  is the degree of  $w(\lambda'_{(i)}) \cdot w(\lambda'_{(i+1)})^p \cdots w(\lambda'_{(m)})^{p^{m-i}}$ . We may express  $t_i$  explicitly as the sum

$$t_i = \sum_{k=i}^m p^{k-i}(p^{\kappa'_k} - 1). \tag{14}$$

Hence one term in the expansion of  $P^{t_i}(W_i(\lambda'))$  using the Cartan formula is  $W_{i-1}(\lambda')$ . We shall complete the proof by using Lemma 2.1 to show that all other terms in the expansion vanish. Thus we have to consider the possible ways to write  $t_i$  so that

$$(p - 1)t_i = \sum_{v=1}^{p-1} \left( \sum_{k=1}^{i-1} (p^{\kappa'_k} - p^{j_{k,v}}) + \sum_{k=i}^m p^{k-i}(p^{\kappa'_k} - p^{j_{k,v}}) \right) \tag{15}$$

where  $0 \leq j_{k,v} \leq \kappa'_k$  for  $1 \leq k \leq m$ . Equating (14) and (15) and simplifying, we obtain

$$(p - 1) \left( \sum_{k=1}^{i-1} p^{\kappa'_k} + \sum_{k=i}^m p^{k-i} \right) = \sum_{v=1}^{p-1} \left( \sum_{k=1}^{i-1} p^{j_{k,v}} + \sum_{k=i}^m p^{k-i} \cdot p^{j_{k,v}} \right). \tag{16}$$

Since  $\kappa$  is column 2-regular,  $\kappa'$  is strictly decreasing and so  $\kappa'_{i-1} > \kappa'_i \geq \kappa'_m + m - i > m - i$ . Hence the  $m$  powers of  $p$  occurring in the left side of (16) are distinct. By uniqueness of base  $p$  expansions, there are also  $m$  distinct powers on the right of (16) and these are a permutation of the powers on the left. The argument is now completed as in the case  $p = 2$  [16, Section 5].  $\square$

We end with evaluations of certain Milnor basis elements on monomials. While [16, Lemma 5.6] generalizes easily to odd primes, this does not seem to be so useful here as the following (weak) generalization of [16, Proposition 5.8].

**Proposition 8.4** *Let  $R = (r_1, r_2, \dots)$  where  $r_i = p - 1$  if  $i = b_1, \dots, b_m$  and  $r_i = 0$  otherwise. Then*

$$P(R)(x_1 \cdots x_n)^{p-1} = \begin{cases} [x_1^{p^{b_1}}, \dots, x_n^{p^{b_n}}]^{p-1} & \text{if } m = n, \\ [x_1, x_2^{p^{b_1}}, \dots, x_n^{p^{b_{n-1}}}]^{p-1} & \text{if } m = n - 1. \end{cases}$$

**Proof** This is proved by induction on  $|R|$ . The base of the induction is Theorem 1.1, which is the case  $m = n - 1$ ,  $b_i = i$  for  $1 \leq i \leq n - 1$ . Given a sequence  $R = (r_1, \dots, r_{j-1}, 0, p - 1, p - 1, \dots, p - 1)$ , let  $R' = (r_1, \dots, r_{j-1}, p - 1, 0, p - 1, \dots, p - 1)$ , so that  $|R| - |R'| = (p - 1)(p^{j+1} - 1) - (p - 1)(p^j - 1) = (p - 1)^2 p^j$ . We claim that  $P^{p^j(p-1)} \cdot P(R')$  and  $P(R)$  have the same value on any polynomial of degree  $n(p - 1)$ . To prove this, we use Milnor’s product formula to expand  $P^{p^j(p-1)} \cdot P(R')$  in the Milnor basis. The Milnor matrix

$$\begin{array}{c|cccccccc} & r_1 & \dots & r_{j-1} & 0 & 0 & p-1 & \dots & p-1 \\ \hline 0 & 0 & \dots & 0 & p-1 & 0 & 0 & \dots & 0 \end{array}$$

shows that  $P(R)$  occurs with coefficient 1 in the product. Since  $P(R)$  is the unique Milnor basis element of minimal excess  $(n - 1)(p - 1)$  in degree  $|R|$ , this proves our claim.

Applying the induction hypothesis to  $P(R')$ , we have  $P(R)(x_1 \dots x_n)^{p-1} = P^{p^j(p-1)} [x_1, x_2^{p^{b_1}}, \dots, x_i^{p^j}, \dots, x_n^{p^{b_{n-1}}}]^{p-1}$  where  $R$  and  $R'$  differ in the  $i$ th term, i.e.  $b_i = j$  for  $R'$  and  $b_i = j + 1$  for  $R$ . By the Cartan formula, this is  $[x_1, x_2^{p^{b_1}}, \dots, x_i^{p^{j+1}}, \dots, x_n^{p^{b_{n-1}}}]^{p-1}$ , and this completes the induction for the case  $m = n - 1$ . The case  $m = n$  is proved similarly.  $\square$

Proposition 8.4 serves as the base of induction for the following generalization of [16, Theorem 5.9(ii)] to odd primes. The proof, by induction on the length of the  $\omega$ -vector  $\sigma$ , is essentially the same as in [16].

**Theorem 8.5** *Let  $R_0 = (r_0, r_1, \dots, r_t)$ ,  $R = (r_1, \dots, r_t)$  and  $f = x_1^{s_1} \cdots x_n^{s_n}$ , where the base  $p$  expansion of each term  $r_i$  and exponent  $s_j$  contains only the digits 0 and  $p - 1$ . Assume that  $f$  and  $R_0$  have the same  $\omega$ -vector  $\sigma$ . Then  $P(R)f = \prod_{k=1}^m \Delta_k^{p^{k-1}(p-1)}$ , where  $m$  is the length of  $\sigma$  and  $\Delta_k = [x_{i_1}^{p^{j_1}}, \dots, x_{i_\kappa}^{p^{j_\kappa}}]$  is the Vandermonde determinant of order  $\kappa = \sigma_k/(p - 1)$  defined by the subsequences  $(s_{i_1}, \dots, s_{i_\kappa})$  of  $(s_1, \dots, s_n)$  and  $(r_{j_1}, \dots, r_{j_\kappa})$  of  $R_0$  consisting of the terms whose  $k$ th base  $p$  place is  $p - 1$ .*

**Example 8.6** Using the tables

$r_0$	$p - 1$	0	$p - 1$	$x_1$	$p - 1$	0	$p - 1$	$r_0$	$p - 1$		
$r_1$	$p - 1$			$x_2$	$p - 1$			$r_1$	$p - 1$	0	$p - 1$
$r_2$	$p - 1$			$x_3$	$p - 1$			$r_2$	$p - 1$		
$\sigma$	$3(p - 1)$	0	$p - 1$	$\sigma$	$3(p - 1)$	0	$p - 1$	$\sigma$	$3(p - 1)$	0	$p - 1$

we obtain  $P(p - 1, p - 1)x_1^{(p^2+1)(p-1)}x_2^{p-1}x_3^{p-1} = [x_1, x_2^p, x_3^p]^{p-1} \cdot x_1^{p^2(p-1)}$  and  $P((p^2 + 1)(p - 1), p - 1)x_1^{(p^2+1)(p-1)}x_2^{p-1}x_3^{p-1} = [x_1, x_2^p, x_3^p]^{p-1} \cdot (x_1^p)^{p^2(p-1)}$ .
