THE MATHEMATICS OF MUTUALLY ALIEN COPIES: FROM GAUSSIAN INTEGRALS TO INTER-UNIVERSAL TEICHMÜLLER THEORY

Shinichi Mochizuki

July 2016

ABSTRACT. **Inter-universal Teichmüller theory** may be described as a construction of certain

canonical deformations of the ring structure of a number field

equipped with certain auxiliary data, which includes an **elliptic curve** over the number field and a **prime number** ≥ 5 . In the present paper, we survey this theory by focusing on the *rich analogies* between this theory and the classical computation of the **Gaussian integral**. The main **common features** that underlie these analogies may be summarized as follows:

- · the introduction of two mutually alien copies of the object of interest;
- · the computation of the effect i.e., on the two mutually alien copies of the object of interest of **two-dimensional changes of coordinates** by considering the effect on **infinitesimals**;
- the passage from planar cartesian to polar coordinates and the resulting splitting, or decoupling, into radial i.e., in more abstract valuation-theoretic terminology, "value group" and angular i.e., in more abstract valuation-theoretic terminology, "unit group" portions;
- · the straightforward evaluation of the **radial portion** by applying the **quadraticity** of the exponent of the Gaussian distribution;
- the straightforward evaluation of the **angular portion** by considering the *metric geometry* of the *group of units* determined by a suitable version of the natural **logarithm** function.

[Here, the intended sense of the descriptive "alien" is that of its original Latin root, i.e., a sense of abstract, tautological "otherness".] After reviewing the classical computation of the Gaussian integral, we give a detailed survey of inter-universal Teichmüller theory by concentrating on the common features listed above. The paper concludes with a discussion of various historical aspects of the mathematics that appears in inter-universal Teichmüller theory.

Introduction

In the present paper, we survey **inter-universal Teichmüller theory** by focusing on the *rich analogies* [cf. §3.8] between this theory and the classical computation of the **Gaussian integral**. Inter-universal Teichmüller theory concerns the construction of

canonical deformations of the ring structure of a number field

equipped with certain auxiliary data. The collection of data, i.e., consisting of the number field equipped with certain auxiliary data, to which inter-universal Teichmüller theory is applied is referred to as **initial** Θ -data [cf. §3.3, (i), for more details]. The principal components of a collection of initial Θ -data are

- · the given number field,
- · an elliptic curve over the number field, and
- · a prime number $l \geq 5$.

The main applications of inter-universal Teichmüller theory to diophantine geometry [cf. §3.7, (iv), for more details] are obtained by applying the *canonical* deformation constructed for a specific collection of initial Θ -data to bound the height of the elliptic curve that appears in the initial Θ -data.

Let N be a fixed natural number > 1. Then the issue of bounding a given nonnegative real number $h \in \mathbb{R}_{\geq 0}$ may be understood as the issue of showing that $N \cdot h$ is **roughly equal** to h, i.e.,

$$N \cdot h$$
 " \approx " h

[cf. §2.3, §2.4]. When h is the **height** of an *elliptic curve* over a number field, this issue may be understood as the issue of showing that the *height* of the [in fact, in most cases, *fictional!*] "*elliptic curve*" whose q-parameters are the N-th powers " q^N " of the q-parameters "q" of the given elliptic curve is **roughly equal** to the height of the given elliptic curve, i.e., that, at least from point of view of [global] heights,

$$q^N$$
 " \approx " q

[cf. $\S 2.3, \S 2.4$].

In order to verify the approximate relation q^N " \approx " q, one begins by introducing **two distinct** — i.e., two "**mutually alien**" — **copies** of the **conventional scheme theory** surrounding the given initial Θ -data. Here, the intended sense of the descriptive "alien" is that of its original Latin root, i.e., a sense of

abstract, tautological "otherness".

These two mutually alien copies of conventional scheme theory are **glued together** — by considering relatively weak underlying structures of the respective conventional scheme theories such as **multiplicative monoids** and **profinite groups** — in such a way that the " q^N " in one copy of scheme theory is **identified** with the "q" in the other copy of scheme theory. This gluing is referred to as the Θ -link. Thus, the " q^N " on the left-hand side of the Θ -link is glued to the "q" on the right-hand side of the Θ -link, i.e.,

$$q_{\mathrm{LHS}}^{N}$$
 "=" q_{RHS}

[cf. §3.3, (vii), for more details]. Here, "N" is in fact taken not to be a fixed natural number, but rather a sort of **symmetrized average** over the values j^2 , where $j = 1, \ldots, l^*$, and we write $l^* \stackrel{\text{def}}{=} (l-1)/2$. Thus, the left-hand side of the above display

$$\{q_{\mathrm{LHS}}^{j^2}\}_j$$

bears a striking formal resemblance to the Gaussian distribution. One then verifies the desired approximate relation q^N " \approx " q by computing

$$\{q_{\mathrm{LHS}}^{j^2}\}_j$$

— **not** in terms of q_{LHS} [which is immediate from the definitions!], but rather — **in terms of** [the scheme theory surrounding]

[which is a highly nontrivial matter!]. The conclusion of this computation may be summarized as follows:

up to relatively mild indeterminacies — i.e., "relatively small error terms" — $\{q_{\text{LHS}}^{j^2}\}_j$ may be "confused", or "identified", with $\{q_{\text{RHS}}^{j^2}\}_j$, that is to say,

$$\{q_{\mathrm{LHS}}^{j^2}\}_j \qquad \stackrel{!!}{\leftrightarrows} \qquad \{q_{\mathrm{RHS}}^{j^2}\}_j$$

$$("=" q_{\mathrm{RHS}})$$

[cf. the discussion of §3.7, (i), especially, Fig. 3.19, for more details]. Once one is equipped with this "license" to confuse/identify $\{q_{\rm LHS}^{j^2}\}_j$ with $\{q_{\rm RHS}^{j^2}\}_j$, the derivation of the desired approximate relation

$$\{q^{j^2}\}_j$$
 "\approx" q

and hence of the desired **bounds** on **heights** is an *essentially formal matter* [cf. §3.7, (ii), (iv)].

The starting point of the exposition of the present paper lies in the *observation* [cf. §3.8 for more details] that the *main features* of the theory underlying the *computation* just discussed of $\{q_{\text{LHS}}^{j^2}\}_j$ in terms of q_{RHS} exhibit **remarkable** similarities — as is perhaps foreshadowed by the *striking formal resemblance* observed above to the *Gaussian distribution* — to the **main features** of the classical computation of the **Gaussian integral**, namely,

- (1^{mf}) the introduction of **two mutually alien copies** of the object of interest [cf. §3.8, (1^{gau}), (2^{gau})];
- (2^{mf}) the computation of the effect i.e., on the two mutually alien copies of the object of interest of **two-dimensional changes of coordinates** by considering the effect on **infinitesimals** [cf. §3.8, (3^{gau}), (4^{gau}), (5^{gau}), (6^{gau})];
- (3^{mf}) the passage from **planar cartesian** to **polar coordinates** and the resulting **splitting**, or **decoupling**, into **radial** i.e., in more abstract valuation-theoretic terminology, "**value group**" and **angular** i.e., in more abstract valuation-theoretic terminology, "**unit group**" portions [cf. §3.8, (7^{gau}), (8^{gau})];
- (4^{mf}) the straightforward evaluation of the **radial portion** by applying the **quadraticity** of the exponent of the Gaussian distribution [cf. §3.8, (9^{gau}), (11^{gau})];
- (5^{mf}) the straightforward evaluation of the **angular portion** by considering the *metric geometry* of the *group of units* determined by a suitable version of the natural **logarithm** function [cf. §3.8, (10^{gau}), (11^{gau})].

The present paper begins, in $\S1$, with a **review** of the classical computation of the **Gaussian integral**, by breaking down this familiar computation into *steps* in such a way as to facilitate the subsequent *comparison* with inter-universal Teichmüller theory. We then proceed, in $\S2$, to discuss the portion of inter-universal Teichmüller theory that corresponds to (2^{mf}) . The exposition of $\S2$ was designed so

as to be accessible to readers familiar with well-known portions of **scheme theory** and the theory of the **étale fundamental group** — i.e., at the level of [Harts] and [SGA1]. The various Examples that appear in this exposition of §2 include numerous

well-defined and relatively straightforward mathematical assertions

often without complete proofs. In particular, the reader may think of the task of supplying a complete proof for any of these assertions as a sort of "exercise" and hence of $\S 2$ itself as a sort of

workbook with exercises.

At the level of papers, §2 is concerned mainly with the content of the "classical" paper [Uchi] of Uchida and the "preparatory papers" [FrdI], [FrdII], [GenEll], [AbsTopII], [AbsTopIII]. By contrast, the level of exposition of §3 is substantially less elementary than that of §2. In §3, we apply the conceptual infrastructure exposed in §2 to survey those aspects of inter-universal Teichmüller theory that correspond to (1^{mf}), (3^{mf}), (4^{mf}), and (5^{mf}), i.e., at the level of papers, to [EtTh], [IUTchII], [IUTchIII], [IUTchIV]. Finally, in §4, we reflect on various historical aspects of the theory exposed in §2 and §3.

Acknowledgements:

The author wishes to express his appreciation for the stimulating comments that he has received from numerous mathematicians concerning the theory exposed in the present paper and, especially, his deep gratitude to Go Yamashita, Mohamed Saïdi, Yuichiro Hoshi, and Ivan Fesenko for the very active and devoted role that they played both in discussing this theory with the author and in disseminating it to others. In particular, the author would like to thank Yuichiro Hoshi for introducing the notion of mono-anabelian transport as a means of formulating a technique that is frequently applied throughout the theory. This notion plays a central role in the expository approach adopted in the present paper.

Section 1: Review of the computation of the Gaussian integral

§1.1. <u>Inter-universal Teichmüller theory via the Gaussian integral</u>: The goal of the present paper is to pave the road, for the reader, from a state of *complete ignorance* of inter-universal Teichmüller theory to a state of *general appreciation* of the "game plan" of inter-universal Teichmüller theory by reconsidering the well-known *computation* of the Gaussian integral

$$\int_{-\infty}^{\infty} e^{-x^2} dx = \sqrt{\pi}$$

via *polar coordinates* from the point of view of a hypothetical high-school student who has studied one-variable calculus and polar coordinates, but has not yet had any exposure to **multi-variable calculus**. That is to say, we shall begin in the present §1 by reviewing this computation of the Gaussian integral by discussing how this computation might be explained to such a hypothetical high-school student. In subsequent §'s, we then proceed to discuss how various **key steps** in

such an explanation to a hypothetical high-school student may be translated into the more sophisticated language of **abstract arithmetic geometry** in such a way as to yield a **general outline** of inter-universal Teichmüller theory based on the *deep structural similarities* between inter-universal Teichmüller theory and the computation of the Gaussian integral.

§1.2. Naive approach via changes of coordinates or partial integrations: In one-variable calculus, definite integrals that appear intractable at first glance are often reduced to much simpler definite integrals by performing suitable *changes of coordinates* or *partial integrations*. Thus:

<u>Step 1</u>: Our hypothetical high-school student might initially be tempted to perform a **change of coordinates**

$$e^{-x^2} \rightsquigarrow u$$

and then [erroneously!] compute

$$\int_{-\infty}^{\infty} e^{-x^2} dx = 2 \cdot \int_{0}^{\infty} e^{-x^2} dx = -\int_{x=0}^{x=\infty} d(e^{-x^2}) = \int_{0}^{1} du = 1$$

— only to realize shortly afterwards that this computation is in error, on account of the **erroneous treatment of the infinitesimal** "dx" when the change of coordinates was executed.

Step 2: This realization might then lead the student to attempt to repair the computation of Step 1 by considering various iterated *partial integrations*

$$\int_{-\infty}^{\infty} e^{-x^2} dx = -\int_{x=-\infty}^{x=\infty} \frac{1}{2x} d(e^{-x^2}) = \int_{x=-\infty}^{x=\infty} e^{-x^2} d\left(\frac{1}{2x}\right) = \dots$$

- which, of course, lead nowhere.
- §1.3. <u>Introduction of identical but mutually alien copies</u>: At this point, one might suggest to the hypothetical high-school student the idea of computing the Gaussian integral by first **squaring** the integral and then taking the **square root** of the value of the square of the integral. That is to say, in effect:
 - <u>Step 3</u>: One might suggest to the hypothetical high-school student that the Gaussian integral can in fact be computed by considering the product of two identical but mutually independent! copies of the Gaussian integral

$$\left(\int_{-\infty}^{\infty} e^{-x^2} dx\right) \cdot \left(\int_{-\infty}^{\infty} e^{-y^2} dy\right)$$

— i.e., as opposed to a *single copy* of the Gaussian integral.

Here, let us recall that our hypothetical high-school student was already in a mental state of extreme frustration as a result of the student's intensive and heroic attempts

in Step 2 which led only to an **endless labyrinth** of meaningless and increasingly complicated mathematical expressions. This experience left our hypothetical high-school student with the impression that the Gaussian integral was without question **by far the most difficult integral** that the student had ever encountered. In light of this experience, the suggestion of Step 3 evoked a reaction of intense **indignation** and **distrust** on the part of the student. That is to say,

the idea that meaningful progress could be made in the computation of such an exceedingly difficult integral simply by considering *two identical copies* of the integral — i.e., as opposed to a *single copy* — struck the student as being utterly **ludicrous**.

Put another way, the suggestion of Step 3 was simply *not* the sort of suggestion that the student wanted to hear. Rather, the student was keenly interested in seeing some sort of **clever partial integration** or **change of coordinates** involving " $\sin(-)$ ", " $\cos(-)$ ", " $\tan(-)$ ", " $\exp(-)$ ", " $\frac{1}{1+x^2}$ ", etc., i.e., of the sort that the student was used to seeing in familiar expositions of **one-variable** calculus.

§1.4. <u>Integrals over two-dimensional Euclidean space</u>: Only after quite substantial efforts at persuasion did our hypothetical high-school student reluctantly agree to proceed to the next step of the explanation:

<u>Step 4</u>: If one considers the "totality", or "total space", of the coordinates that appear in the product of two copies of the Gaussian integral of Step 3, then one can regard this product of integrals as a single integral

$$\int_{\mathbb{R}^2} e^{-x^2} \cdot e^{-y^2} dx dy = \int_{\mathbb{R}^2} e^{-(x^2 + y^2)} dx dy$$

over the **Euclidean plane** \mathbb{R}^2 .

Of course, our hypothetical high-school student might have some trouble with Step 4 since it requires one to assimilate the notion of an **integral** over a space, i.e., the *Euclidean plane* \mathbb{R}^2 , which is not an interval of the real line. This, however, may be explained by reviewing the essential philosophy behind the notion of the **Riemann integral** — a philosophy which should be familiar from **one-variable calculus**:

<u>Step 5</u>: One may think of integrals over more general spaces, i.e., such as the Euclidean plane \mathbb{R}^2 , as computations

$$net\ mass\ =\ \lim\ \sum\ (\text{infinitesimals of }zero\ mass)$$

of "net mass" by considering *limits of sums of* infinitesimals, i.e., such as "dx dy", which one may think of as having "zero mass".

§1.5. The effect on infinitesimals of changes of coordinates: Just as in one-variable calculus, computations of integrals over more general spaces can often be *simplified* by performing suitable *changes of coordinates*. Any [say, continuously differentiable] change of coordinates results in a *new factor*, given by the **Jacobian**, in the integrand. This factor constituted by the Jacobian, i.e., the determinant of a certain *matrix of partial derivatives*, may appear to be somewhat *mysterious* to our

hypothetical high-school student, who is only familiar with changes of coodinates in one-variable calculus. On the other hand, the appearance of the Jacobian may be justified in a *computational fashion* as follows:

Step 6: Let $U, V \subseteq \mathbb{R}^2$ be open subsets of \mathbb{R}^2 and

$$U \ni (s,t) \mapsto (x,y) = (f(s,t),g(s,t)) \in V$$

a continuously differentiable change of coordinates such that the Jacobian

 $J \stackrel{\text{def}}{=} \det \begin{pmatrix} \frac{\partial f}{\partial s} & \frac{\partial f}{\partial t} \\ \frac{\partial g}{\partial s} & \frac{\partial g}{\partial t} \end{pmatrix}$

— which may be thought of as a continuous real-valued function on U — is nonzero throughout U. Then for any continuous real-valued functions $\phi: U \to \mathbb{R}, \ \psi: V \to \mathbb{R}$ such that $\psi(f(s,t),g(s,t)) = \phi(s,t)$, the effect of the above change of coordinates on the integral of ψ over V may be computed as follows:

$$\int_{V} \psi \ dx \ dy = \int_{U} \phi \cdot J \ ds \ dt.$$

Step 7: In the situation of Step 6, the effect of the change of coordinates on the "infinitesimals" dx dy and ds dt may be understood as follows: First, one localizes to a sufficiently small open neighborhood of a point of U over which the various partial derivatives of f and g are roughly constant, which implies that the change of coordinates determined by f and g is roughly linear. Then the effect of such a linear transformation on areas — i.e., in the language of Step 5, "masses" — of sufficiently small parallelograms is given by multiplying by the determinant of the linear transformation. Indeed, to verify this, one observes that, after possible pre- and post-composition with a rotation [which clearly does not affect the computation of such areas], one may assume that one of the sides of the parallelogram under consideration is a line segment on the saxis whose left-hand endpoint is equal to the origin (0,0), and, moreover, that the linear transformation may be written as a composite of toral dilations and unipotent linear transformations of the form

$$(s,t) \mapsto (a \cdot s, b \cdot t); \qquad (s,t) \mapsto (s+c \cdot t, t)$$

— where $a, b, c \in \mathbb{R}$, and $ab \neq 0$. On the other hand, in the case of such "upper triangular" linear transformations, the effect of the linear transformation on the area of the parallelogram under consideration is an easy computation at the level of high-school planar geometry.

§1.6. Passage from planar cartesian to polar coordinates: Once the "innocuous" generalities of Steps 5, 6, and 7 have been assimilated, one may proceed as follows:

<u>Step 8</u>: We apply Step 6 to the integral of Step 4, regarded as an integral over the complement $\mathbb{R}^2 \setminus (\mathbb{R}_{\leq 0} \times \{0\})$ of the negative x-axis in the Euclidean plane, to the change of coordinates

$$\mathbb{R}_{>0} \times (-\pi, \pi) \ni (r, \theta) \mapsto (x, y) = (r \cos(\theta), r \sin(\theta)) \in \mathbb{R}^2 \setminus (\mathbb{R}_{<0} \times \{0\})$$

— where we write $\mathbb{R}_{>0}$ for the set of positive real numbers and $(-\pi, \pi)$ for the open interval of real numbers between $-\pi$ and π .

Step 9: The change of coordinates of Step 8 allows one to compute as follows:

$$\left(\int_{-\infty}^{\infty} e^{-x^2} dx\right) \cdot \left(\int_{-\infty}^{\infty} e^{-y^2} dy\right) = \int_{\mathbb{R}^2} e^{-x^2} \cdot e^{-y^2} dx dy$$

$$= \int_{\mathbb{R}^2} e^{-(x^2 + y^2)} dx dy$$

$$= \int_{\mathbb{R}^2 \setminus (\mathbb{R}_{\le 0} \times \{0\})} e^{-(x^2 + y^2)} dx dy$$

$$= \int_{\mathbb{R}_{>0} \times (-\pi, \pi)} e^{-r^2} r dr d\theta$$

$$= \left(\int_{0}^{\infty} e^{-r^2} \cdot 2r dr\right) \cdot \left(\int_{-\pi}^{\pi} \frac{1}{2} \cdot d\theta\right)$$

— where we observe that the *final equality* is notable in that it shows that, in the computation of the integral under consideration, the **radial** [i.e., "r"] and **angular** [i.e., " θ "] coordinates may be **decoupled**, i.e., that the integral under consideration may be written as a product of a *radial integral* and an *angular integral*.

Step 10: The radial integral of Step 9 may be evaluated

$$\int_0^\infty e^{-r^2} \cdot 2r dr = \int_0^1 d(e^{-r^2}) = \int_0^1 du = 1$$

by applying the change of coordinates

$$e^{-r^2} \rightsquigarrow u$$

that, in essence, appeared in the erroneous initial computation of Step 1!

Step 11: The angular integral of Step 9 may be evaluated as follows:

$$\int_{-\pi}^{\pi} \frac{1}{2} \cdot d\theta = \pi$$

Here, we note that, if one thinks of the Euclidean plane \mathbb{R}^2 of Step 4 as the *complex plane*, i.e., if we write the change of coordinates of Step 8 in

the form $x + iy = r \cdot e^{i\theta}$, then, relative to the Euclidean coordinates (x, y) of Step 4, the above evaluation of the angular integral may be regarded as arising from the **change of coordinates** given by considering the *imaginary part* of the **natural logarithm**

$$\log(r \cdot e^{i\theta}) = \log(r) + i\theta.$$

Step 12: Thus, in summary, we conclude that

$$\left(\int_{-\infty}^{\infty} e^{-x^2} dx\right)^2 = \left(\int_{-\infty}^{\infty} e^{-x^2} dx\right) \cdot \left(\int_{-\infty}^{\infty} e^{-y^2} dy\right)$$
$$= \left(\int_{0}^{\infty} e^{-r^2} \cdot 2r dr\right) \cdot \left(\int_{-\pi}^{\pi} \frac{1}{2} \cdot d\theta\right) = \pi$$

— i.e., that
$$\int_{-\infty}^{\infty} e^{-x^2} dx = \sqrt{\pi}$$
.

§1.7. <u>Justification of naive approach up to an "error factor"</u>: Put another way, the content of the above discussion may be summarized as follows:

If one considers two identical — but mutually independent! — copies of the Gaussian integral, i.e., as opposed to a *single copy*, then the naively motivated coordinate transformation that gave rise to the erroneous computation of Step 1 may be "justified", up to a suitable "error factor" $\sqrt{\pi}$!

Section 2: Changes of universe as arithmetic changes of coordinates

§2.1. The issue of bounding heights: the ABC and Szpiro Conjectures: In diophantine geometry, i.e., more specifically, the diophantine geometry of rational points of an algebraic curve over a number field [i.e., an "NF"], one is typically concerned with the issue of **bounding heights** of such rational points. A brief exposition of various *conjectures* related to this issue of bounding heights of rational points may be found in [Fsk], §1.3. In this context, the case where the algebraic curve under consideration is the projective line minus three points corresponds most directly to the so-called ABC and — by thinking of this projective line as the " λ -line" that appears in discussions of the **Legendre form** of the Weierstrass equation for an elliptic curve — Szpiro Conjectures. In this case, the height of a rational point may be thought of as a suitable weighted sum of the valuations of the q-parameters of the elliptic curve determined by the rational point at the nonarchimedean primes of potentially multiplicative reduction [cf. the discussion at the end of [Fsk], §2.2; [GenEll], Proposition 3.4]. Here, it is also useful to recall [cf. [GenEll], Theorem 2.1] that, in the situation of the ABC or Szpiro Conjectures, one may assume, without loss of generality, that, for any given finite set Σ of [archimedean and nonarchimedean] valuations of the rational number field \mathbb{Q} ,

the rational points under consideration lie, at each valuation of Σ , inside some **compact subset** [i.e., of the set of rational points of the projective

line minus three points over *some finite extension of the completion* of \mathbb{Q} at this valuation] satisfying certain properties.

In particular, when one computes the height of a rational point of the projective line minus three points as a suitable weighted sum of the valuations of the q-parameters of the corresponding elliptic curve, one may **ignore**, up to bounded discrepancies, contributions to the height that arise, say, from the **archimedean valuations** or from the nonarchimedean valuations that lie over some "exceptional" prime number such as 2.

§2.2. Arithmetic degrees as global integrals: As is well-known, the height of a rational point may be thought of as the arithmetic degree of a certain arithmetic line bundle over the field of definition of the rational point [cf. [Fsk], §1.3; [GenEll], §1]. Alternatively, from an idèlic point of view, such arithmetic degrees of arithmetic line bundles over an NF may be thought of as logarithms of volumes — i.e., "log-volumes" — of certain regions inside the ring of adèles of the NF [cf. [Fsk], §2.2; [AbsTopIII], Definition 5.9, (iii); [IUTchIII], Proposition 3.9, (iii)]. Relative to the point of view of the discussion of §1.4, such log-volumes may be thought of as "net masses", that is to say,

as "global masses" [i.e., global log-volumes] that arise by summing up various "local masses" [i.e., local log-volumes], corresponding to the [archimedean and nonarchimedean] valuations of the NF under consideration.

This point of view of the discussion of §1.4 suggests further that such a global net mass should be regarded as some sort of

integral over an NF, that is to say, which arises by applying some sort of mysterious "limit summation operation" to some sort of "zero mass infinitesimal" object [i.e., corresponding a differential form].

It is precisely this point of view that will be pursued in the discussion to follow via the following correspondences with terminology to be explained below:

zero mass objects ←→ "étale-like" structures
positive/non-zero mass objects ←→ "Frobenius-like" structures

§2.3. Bounding heights via global multiplicative subspaces: In the situation discussed in §2.1, one way to understand the problem of showing that the height $h \in \mathbb{R}$ of a rational point is "small" is as the problem of showing that, for some fixed natural number N > 1, the height h satisfies the equation

$$N \cdot h \stackrel{\text{def}}{=} h + h + \dots + h = h$$

[which implies that h = 0!] — or, more generally, for a suitable "relatively small" constant $C \in \mathbb{R}$ [i.e., which is independent of the rational point under consideration], the **inequality**

$$N \cdot h < h + C$$

[which implies that $h \leq \frac{1}{N-1} \cdot C!$] — holds. Indeed, this is precisely the approach that is taken to bounding heights in the "tiny" special case of the theory of [Falt1]

that is given in the proof of [GenEll], Lemma 3.5. Here, we recall that the key assumption in [GenEll], Lemma 3.5, that makes this sort of argument work is the assumption of the existence, for some prime number l, of a certain kind of special rank one subspace [i.e., a subspace whose \mathbb{F}_l -dimension is equal to 1] of the space of l-torsion points [i.e., a \mathbb{F}_l -vector space of dimension 2] of the elliptic curve under consideration. Such a rank one subspace is typically referred to in this context as a **global multiplicative subspace**, i.e., since it is a subspace defined over the NF under consideration that coincides, at each nonarchimedean valuation of the NF at which the elliptic curve under consideration has potentially multiplicative reduction, with the rank one subspace of l-torsion points that arises, via the Tate uniformization, from the [one-dimensional] space of l-torsion points of the multiplicative group $\mathbb{G}_{\mathbf{m}}$. The quotient of the original given elliptic curve by such a global multiplicative subspace is an elliptic curve that is **isogenous** to the original elliptic curve. Moreover,

the q-parameters of this isogenous elliptic curve are the l-th powers of the q-parameters of the original elliptic curve; thus, the **height** of this isogenous elliptic curve is [roughly, up to contributions of negligible order] l times the height of the original elliptic curve.

These properties of the isogenous elliptic curve allow one to **compute** the height of the isogenous elliptic curve in terms of the height of the original elliptic curve by calculating the effect of the isogeny relating the two elliptic curves on the respective **sheaves of differentials** and hence to conclude an inequality " $N \cdot h \leq h + C$ " of the desired type [for N = l — cf. the proof of [GenEll], Lemma 3.5, for more details]. At a more concrete level, this computation may be summarized as the **observation** that, by considering the effect of the isogeny under consideration on sheaves of differentials, one may conclude that

"multiplying heights by l — i.e., "raising **q**-parameters to the **l**-th power" $q \mapsto q^l$

— has the effect on logarithmic differential forms

$$d\log(q) = \frac{dq}{q} \mapsto l \cdot d\log(q)$$

of multiplying by l, i.e., at the level of **heights**, of **adding** terms of the order of $\log(l)$, thus giving rise to inequalities that are roughly of the form " $l \cdot h \leq h + \log(l)$ ".

On the other hand, in general,

such a global multiplicative subspace *does not exist*, and the issue of somehow "simulating" the existence of a global multiplicative subspace is one fundamental theme of inter-universal Teichmüller theory.

§2.4. Bounding heights via Frobenius morphisms on number fields: The simulation issue discussed in §2.3 is, in some sense, the fundamental reason for the construction of various types of "Hodge theaters" in [IUTchI] [cf. the discussion surrounding [IUTchI], Fig. I1.4; [IUTchI], Remark 4.3.1]. From the point of view of the present discussion, the fundamental additive and multiplicative symmetries that appear in the theory of $\Theta^{\pm \text{ell}}NF$ - Θ

§3.6, (i), below] and which correspond, respectively, to the *additive* and *multi*plicative structures of the ring \mathbb{F}_l [where l is the fixed prime number for which we consider l-torsion points], may be thought of as corresponding, respectively, to the symmetries in the equation

$$N \cdot h \stackrel{\text{def}}{=} h + h + \dots + h = h$$

of all the h's [in the case of the additive symmetry] and of the h's on the LHS [in the case of the multiplicative symmetry]. This portion of inter-universal Teichmüller theory is closely related to the analogy between inter-universal Teichmüller theory and the classical hyperbolic geometry of the upper half-plane. This analogy with the hyperbolic geometry of the upper half-plane is, in some sense, the central topic of [BogIUT] and may be thought of as corresponding to the portion of inter-universal Teichmüller theory discussed in [IUTchI], [IUTchIII]. Since this aspect of inter-universal Teichmüller theory is already discussed in substantial detail in [BogIUT], we shall not discuss it in much detail in the present paper. On the other hand, another way of thinking about the above equation " $N \cdot h = h$ " is as follows:

This equation may also be thought of as calling for the establishment of some sort of analogue for an **NF** of the **Frobenius morphism** in positive characteristic scheme theory, i.e., a Frobenius morphism that somehow "acts" naturally on the entire situation [i.e., including the height h, as well as the q-parameters at nonarchimedean valuations of potentially multiplicative reduction, of a given elliptic curve over the NF] in such a way as to multiply arithmetic degrees [such as the height!] by N and raise q-parameters to the N-th power — i.e.,

$$h \mapsto N \cdot h, \quad q \mapsto q^N$$

— and hence yield the equation " $N \cdot h = h$ " [or inequality " $N \cdot h \leq h + C$ "] via some sort of natural functoriality.

This point of view is also quite **fundamental** to inter-universal Teichmüller theory, and, in particular, to the analogy between inter-universal Teichmüller theory and the theory of the **Gaussian integral**, as reviewed in §1. These aspects of inter-universal Teichmüller theory are discussed in [IUTchII], [IUTchIII]. In the present paper, we shall concentrate mainly on the exposition of these aspects of inter-universal Teichmüller theory. Before proceeding, we remark that, ultimately, in inter-universal Teichmüller theory, we will, in effect, take "N" to be a sort of **symmetrized average** over the **squares** of the values $j = 1, 2, ..., l^*$, where $l^* = (l-1)/2$, and l is the prime number of §2.3. That is to say, whereas the [purely hypothetical!] **naive analogue** of the **Frobenius morphism** for an NF considered so far has the effect, on q-parameters of the elliptic curve under consideration at nonarchimedean valuations of potentially multiplicative reduction, of mapping $q \mapsto q^N$, the sort of assignment that we shall ultimately be interested in inter-universal Teichmüller theory is an assignment [which is in fact typically written with the *left*- and *right*- hand sides *reversed*|

$$\underline{\underline{q}} \mapsto \{\underline{\underline{q}}^{j^2}\}_{j=1,\dots,l^*}$$

— where $\underline{\underline{q}}$ denotes a 2l-th root of the q-parameter q — i.e., an assignment which, at least at $\underline{\underline{q}}$ formal level, closely resembles a **Gaussian distribution**. Of course,

such an assignment is **not compatible** with the **ring structure** of an NF, hence does not exist in the **framework** of **conventional scheme theory**. Thus, one way to understand inter-universal Teichmüller theory is as follows:

in some sense the fundamental theme of inter-universal Teichmüller theory consists of the development of a mechanism for **computing** the effect — e.g., on heights of elliptic curves [cf. the discussion of §2.3!] — of such non-scheme-theoretic "Gaussian Frobenius morphisms" on NF's.

§2.5. Fundamental example of the derivative of a Frobenius lifting: In some sense, the most fundamental example of the sort of Frobenius action in the p-adic theory [cf. the discussion of §2.5] that one would like to somehow translate into the case of **NF**'s is the following [cf. [AbsTopII], Remark 2.6.2; [AbsTopIII], §15; [IUTchIII], Remark 3.12.4, (v)]:

Example 2.5.1: Frobenius liftings on smooth proper curves. Let p be a prime number; A the ring of Witt vectors of a perfect field k of characteristic p; X a smooth, proper curve over A of genus $g_X \geq 2$; $\Phi: X \to X$ a Frobenius lifting, i.e., a morphism whose reduction modulo p coincides with the Frobenius morphism in characteristic p. Thus, one verifies immediately that Φ necessarily lies over the Frobenius morphism on the ring of Witt vectors A. Write ω_{X_k} for the sheaf of differentials of $X_k \stackrel{\text{def}}{=} X \times_A k$ over k. Then the **derivative** of Φ yields, upon dividing by p, a morphism of line bundles

$$\Phi^*\omega_{X_k} \to \omega_{X_k}$$

which is easily verified to be *generically injective*. Thus, by taking *global degrees of line bundles*, we obtain an **inequality**

$$(p-1)(2g_X-2) \leq 0$$

— hence, in particular, an inequality $g_X \leq 1$ — which may be thought of as being, in essence, a statement to the effect that X is **cannot be hyperbolic**. Note that, from the point of view discussed in §1.4, §1.5, §2.2, §2.3, §2.4, this inequality may be thought of as

a computation of "global net masses", i.e., global degrees of line bundles on X_k , via a computation of the effect of the "change of coordinates" Φ by considering the effect of this change of coordinates on "infinitesimals", i.e., on the sheaf of differentials ω_{X_k} .

§2.6. Positive characteristic model for mono-anabelian transport: One fundamental drawback of the computation discussed in Example 2.5.1 is that it involves the operation of differentiation on X_k , an operation which does not, at least in the immediate literal sense, have a natural analogue in the case of NF's. This drawback does not exist in the following example, which treats certain subtle, but well-known aspects of anabelian geometry in positive characteristic and, moreover, may, in some sense, be regarded as the fundamental model, or prototype, for a quite substantial portion of inter-universal Teichmüller theory. In this example, Galois groups, or étale fundamental groups, in some sense play

the role that is played by **tangent bundles** in the classical theory — a situation that is reminiscent of the approach of the [scheme-theoretic] **Hodge-Arakelov theory** of [HASurI], [HASurII], which is briefly reviewed in §2.14 below. One notion of central importance in this example — and indeed throughout inter-universal Teichmüller theory! — is the notion of a **cyclotome**, a term which is used to refer to an isomorphic copy of some quotient [by a closed submodule] of the familiar Galois module " $\widehat{\mathbb{Z}}(1)$ ", i.e., the "Tate twist" of the trivial Galois module " $\widehat{\mathbb{Z}}$ ", or, alternatively, the rank one free $\widehat{\mathbb{Z}}$ -module equipped with the action determined by the **cyclotomic character**. Also, if p is a prime number, then we shall write $\widehat{\mathbb{Z}}_{\neq p}$ for the quotient $\widehat{\mathbb{Z}}/\mathbb{Z}_p$.

<u>Example 2.6.1</u>: Mono-anabelian transport via the Frobenius morphism in positive characteristic.

(i) Let p be a prime number; k a finite field of characteristic p; X a smooth, proper curve over k of genus $g_X \geq 2$; K the function field of X; \widetilde{K} a separable closure of K. Write $\eta_X \stackrel{\text{def}}{=} \operatorname{Spec}(K)$; $\widetilde{\eta}_X \stackrel{\text{def}}{=} \operatorname{Spec}(\widetilde{K})$; $\overline{k} \subseteq \widetilde{K}$ for the algebraic closure of k determined by \widetilde{K} ; $\mu_{\overline{k}} \subseteq \overline{k}$ for the group of roots of unity of \overline{k} ; $\mu_{\overline{k}}^{\mathbb{Z}_{\neq p}} \stackrel{\text{def}}{=} \operatorname{Gal}(\mathbb{Q}/\mathbb{Z}, \mu_{\overline{k}})$; $G_K \stackrel{\text{def}}{=} \operatorname{Gal}(\widetilde{K}/K)$; $G_k \stackrel{\text{def}}{=} \operatorname{Gal}(\overline{k}/k)$; Π_X for the quotient of G_K determined by the maximal subextension of \widetilde{K} that is unramified over X;

$$\Phi_X: X \to X, \quad \Phi_{\eta_X}: \eta_X \to \eta_X, \quad \Phi_{\widetilde{\eta}_X}: \widetilde{\eta}_X \to \widetilde{\eta}_X$$

for the respective Frobenius morphisms of X, η_X , $\widetilde{\eta}_X$. Thus, we have natural surjections $G_K \to \Pi_X \to G_k$, and Π_X may be thought of as [i.e., is naturally isomorphic to] the étale fundamental group of X [for a suitable choice of basepoint]. Write $\Delta_X \stackrel{\text{def}}{=} \text{Ker}(\Pi_X \to G_k)$. Recall that it follows from elementary facts concerning separable and purely inseparable field extensions that [by considering $\Phi_{\widetilde{\eta}_X}$] Φ_{η_X} induces isomorphisms of Galois groups and étale fundamental groups

$$\Psi_X:\Pi_X\stackrel{\sim}{\to}\Pi_X,\quad \Psi_{\eta_X}:G_K\stackrel{\sim}{\to}G_K$$

— which is, in some sense, a quite remarkable fact since

the Frobenius morphisms Φ_X , Φ_{η_X} themselves are morphisms "of degree p > 1", hence, in particular, are by no means isomorphisms!

We refer to [IUTchIV], Example 3.6, for a more general version of this phenomenon.

(ii) Next, let us recall that it follows from the fundamental anabelian results of [Uchi] that there exists a purely group-theoretic functorial algorithm

$$G_K \mapsto \widetilde{K}(G_K)^{\text{CFT}} \curvearrowleft G_K$$

— i.e., an algorithm whose input data is the abstract topological group G_K , whose **functoriality** is with respect to isomorphisms of topological groups, and whose output data is a field $\widetilde{K}(G_K)^{\text{CFT}}$ equipped with a G_K -action. Moreover, if one allows oneself to apply the conventional interpretation of G_K as a Galois group $\text{Gal}(\widetilde{K}/K)$, then there is a natural G_K -equivariant isomorphism

$$\rho: \widetilde{K} \stackrel{\sim}{\to} \widetilde{K}(G_K)^{\operatorname{CFT}}$$

that arises from the **reciprocity map** of **class field theory**, applied to each of the finite subextensions of the extension \widetilde{K}/K . Since class field theory depends, in an essential way, on the *field structure* of \widetilde{K} and K, it follows formally that, at least in an *a priori* sense, the construction of ρ itself also depends, in an essential way, on the **field structure** of \widetilde{K} and K. Moreover, the fact that the isomorphism $\widetilde{K}(\Psi_{\eta_X})^{\text{CFT}} : \widetilde{K}(G_K)^{\text{CFT}} \xrightarrow{\sim} \widetilde{K}(G_K)^{\text{CFT}}$ and ρ are [unlike Φ_{η_X} itself!] isomorphisms implies that the diagram

$$\widetilde{K}(G_K)^{\text{CFT}} \stackrel{\widetilde{K}(\Psi_{\eta_X})^{\text{CFT}}}{\longleftarrow} \widetilde{K}(G_K)^{\text{CFT}}$$

$$\uparrow^{\rho} \qquad \curvearrowright ? \qquad \uparrow^{\rho}$$

$$\widetilde{K} \stackrel{\Phi_{\eta_X}^*}{\longrightarrow} \qquad \widetilde{K}$$

fails to be commutative!

(iii) On the other hand, let us recall that consideration of the first Chern class of a line bundle of degree 1 on X yields a natural isomorphism

$$\lambda: \boldsymbol{\mu}_{\overline{k}}^{\widehat{\mathbb{Z}}_{\neq p}} \overset{\sim}{\to} M_X \overset{\text{def}}{=} \operatorname{Hom}_{\widehat{\mathbb{Z}}_{\neq p}}(H^2(\Delta_X, \widehat{\mathbb{Z}}_{\neq p}), \widehat{\mathbb{Z}}_{\neq p})$$

[cf., e.g., [Cusp], Proposition 1.2, (ii)]. Such a natural isomorphism between cyclotomes [i.e., such as $\mu_{\overline{k}}^{\widehat{\mathbb{Z}}_{\neq p}}$, M_X] will be referred to as a cyclotomic rigidity isomorphism. Thus, if we let "H" range over the open subgroups of G_K , then, by composing this cyclotomic rigidity isomorphism [applied to the coefficients of " $H^1(-)$ "] with the **Kummer morphism** associated to the multiplicative group $(\widetilde{K}^H)^{\times}$ of the field \widetilde{K}^H of H-invariants of \widetilde{K} , we obtain an embedding

$$\kappa: \widetilde{K}^{\times} \hookrightarrow \underline{\lim}_{H} H^{1}(H, \boldsymbol{\mu}_{\overline{k}}^{\widehat{\mathbb{Z}}_{\neq p}}) \overset{\sim}{\to} \underline{\lim}_{H} H^{1}(H, M_{X})$$

— whose construction depends only on the **multiplicative monoid** with G_K -action \widetilde{K}^{\times} and the **cyclotomic rigidity isomorphism** λ . Note that the existence of the reconstruction algorithm $\widetilde{K}(-)^{\text{CFT}}$ reviewed above implies that the kernels of the natural surjections $G_K \to \Pi_X \to G_k$ may be reconstructed group-theoretically from the abstract topological group G_K . In particular, we conclude that $\varinjlim_H H^1(H, M_X)$ may be reconstructed group-theoretically from the abstract topological group G_K . Moreover, the *anabelian* theory of [Cusp] [cf., especially, [Cusp], Proposition 2.1; [Cusp], Theorem 2.1, (ii); [Cusp], Theorem 3.2] yields a **purely group-theoretic functorial algorithm**

$$G_K \mapsto \widetilde{K}(G_K)^{\mathrm{Kum}} \curvearrowleft G_K$$

— i.e., an algorithm whose input data is the abstract topological group G_K , whose functoriality is with respect to isomorphisms of topological groups, and whose output data is a field $\widetilde{K}(G_K)^{\text{Kum}}$ equipped with a G_K -action which is constructed as the union with $\{0\}$ of the image of κ . [In fact, the input data for this algorithm may be taken to be the abstract topological group Π_X , but we shall not pursue

this topic here.] Thus, just as in the case of " $\widetilde{K}(-)^{\text{CFT}}$ ", the fact that the isomorphism $\widetilde{K}(\Psi_{\eta_X})^{\text{Kum}} : \widetilde{K}(G_K)^{\text{Kum}} \stackrel{\sim}{\to} \widetilde{K}(G_K)^{\text{Kum}}$ and κ are [unlike Φ_{η_X} itself!] isomorphisms implies that the diagram

$$\widetilde{K}(G_K)^{\operatorname{Kum}} \stackrel{\widetilde{K}(\Psi_{\eta_X})^{\operatorname{Kum}}}{\longleftarrow} \widetilde{K}(G_K)^{\operatorname{Kum}}$$

$$\uparrow^{\kappa} \qquad \curvearrowright ? \qquad \uparrow^{\kappa}$$

$$\widetilde{K} \stackrel{\Phi_{\eta_X}^*}{\longrightarrow} \qquad \widetilde{K}$$

— where, by a slight abuse of notation, we write " κ " for the "formal union" of κ with " $\{0\}$ " — fails to be commutative!

- (iv) The [a priori] noncommutativity of the diagram of the final display of (iii) may be interpreted in two ways, as follows:
 - (a) If one starts with the assumption that this diagram is in fact commutative, then the fact that the Frobenius morphism $\Phi_{\eta_X}^*$ multiplies degrees of rational functions $\in K$ by p, together with the fact that the vertical and upper horizontal arrows of the diagram are isomorphisms, imply [since the field K is not perfect! the erroneous conclusion that all degrees of rational functions $\in \overline{K}$ are equal to zero! This sort of argument is formally similar to the argument " $N \cdot h = h \implies h = 0$ " discussed in §2.3.
 - (b) One may regard the noncommutativity of this diagram as the **problem** of computing just how much "indeterminacy" one must allow in the objects and arrows that appear in the diagram in order to render the diagram commutative. From this point of view, one verifies immediately that a **solution** to this problem may be given by introducing "indeterminacies" as follows: One replaces

$$\lambda \rightsquigarrow \lambda \cdot p^{\mathbb{Z}}$$

the cyclotomic rigidity isomorphism λ by the orbit of λ with respect to composition with multiplication by arbitrary \mathbb{Z} -powers of p, and one replaces

$$\widetilde{K} \leadsto \widetilde{K}^{\mathrm{pf}}, \quad \widetilde{K}(G_K)^{\mathrm{Kum}} \leadsto (\widetilde{K}(G_K)^{\mathrm{Kum}})^{\mathrm{pf}}$$

the fields \widetilde{K} , $\widetilde{K}(G_K)^{\text{Kum}}$ by their **perfections**.

Here, we observe that interretation (b) may be regarded as corresponding to the argument " $N \cdot h \leq h + C \implies h \leq \frac{1}{N-1} \cdot C$ " discussed in §2.3. That is to say,

If, in the situation of (b), one can show that the **indeterminacies** necessary to render the diagram commutative are sufficiently mild, at least in the case of the heights or q-parameters that one is interested in, then it is "reasonable to expect" that the resulting "contradiction in the style of interpretation (a)" between

multiplying degrees by some integer [or rational number] > 1and the fact that

> the vertical and upper horizontal arrows of the diagram are isomorphisms

should enable one to conclude that " $N \cdot h \leq h + C$ " [and hence that " $h \leq \frac{1}{N-1} \cdot C$ "].

This is precisely the approach that is in fact taken in inter-universal Teichmüller theory.

- §2.7. The apparatus and terminology of mono-anabelian transport: Example 2.6.1 is exceptionally rich in structural similarities to inter-universal Teichmüller theory, which we proceed to explain in detail as follows. One way to understand these structural similarities is by considering the quite substantial portion of terminology of inter-universal Teichmüller theory that was, in essence, inspired by Example 2.6.1:
- (i) <u>Links between "mutually alien" copies of scheme theory:</u> One central aspect of inter-universal Teichmüller theory is the study of certain "walls", or "filters" which are often referred to as "links" that separate two "mutually alien" copies of conventional scheme theory [cf. the discussions of [IUTchII], Remark 3.6.2; [IUTchIV], Remark 3.6.1]. The main example of such a link in inter-universal Teichmüller theory is constituted by [various versions of] the Θ -link. The log-link also plays an important role in inter-universal Teichmüller theory. The main motivating example for these links which play a central role in inter-universal Teichmüller theory is the **Frobenius morphism** Φ_{η_X} of Example 2.6.1. From the point of view of the discussion of §1.4, §1.5, §2.2, §2.3, §2.4, and §2.5, such a link corresponds to a **change of coordinates**.
- (ii) Frobenius-like objects: The objects that appear on either side of a link and which are used in order to construct, or "set up", the link, are referred to as "Frobenius-like". Thus, in Example 2.6.1, the "mutually alien" copies of \widetilde{K} on either side of the p-power map $\Phi_{\eta_X}^*$ are Frobenius-like. Typically, Frobenius-like structures are characterized by the fact that they have positive/non-zero mass. That is to say, Frobenius-like structures represent the positive mass i.e., such as degrees of rational functions in Example 2.6.1 or heights/degrees of arithmetic line bundles in the context of diophantine geometry that one is ultimately interested in computing and, moreover, is, at least in an a priori sense, affected in a nontrivial way, e.g., multiplied by some factor > 1, by the link under consideration. From this point of view, Frobenius-like objects are characterized by the fact that the link under consideration gives rise to an "ordering", or "asymmetry", between Frobenius-like objects in the domain and codomain of the link under consideration [cf. the discussion of [FrdI], §I3, §I4].
- (iii) Étale-like objects: By contrast, objects that appear on either side of a link that correspond to some sort of "underlying topology" such as the étale topology! are referred to as "étale-like". Typically, étale-like structures are mapped isomorphically albeit via some indeterminate isomorphism! [cf. the discussion of §2.10 below] to one another by the link under consideration. From this point of view, étale-like objects are characterized by the fact that the link under consideration gives rise to a "confusion", or "symmetry", between étale-like objects in the domain and codomain of the link under consideration [cf. the discussion of [FrdI], §I3, §I4]. Thus, in Example 2.6.1, the Galois groups/étale fundamental groups G_K , Π_X , which are mapped isomorphically to one another via Φ_{n_X} , albeit via some "mysterious indeterminate isomorphism", are étale-like.

Objects that are algorithmically constructed from étale-like objects such as G_K or Π_X are also referred to as étale-like, so long as they are regarded as being equipped with the additional structure constituted by the algorithm applied to construct the object from some object such as G_K or Π_X . Etale-like structures are regarded as having zero mass and are used as rigid containers for positive mass Frobenius-like objects, i.e., containers whose rigidity typically arises from various anabelian properties and [as in Example 2.6.1!] allows one to compute the effect on positive mass Frobenius-like objects of the links, or "changes of coordinates", under consideration.

(iv) Coric objects: In the context of consideration of some sort of link as in (i), **coricity** refers to the property of being *invariant* with respect to the link under consideration. Thus, as discussed in (iii), étale-like objects, considered up to isomorphism, constitute a primary example of the notion of a coric object. On the other hand, Frobenius-like coric objects also arise naturally in various contexts. Indeed, in the situation of Example 2.6.1 [cf. the discussion of Example 2.6.1, (iv), (b)], not only étale-like objects such as Π_X , G_K , and $\widetilde{K}(G_K)^{\text{Kum}}$, but also Frobenius-like objects such as the perfections $\widetilde{K}^{\mathrm{pf}}$ are coric.

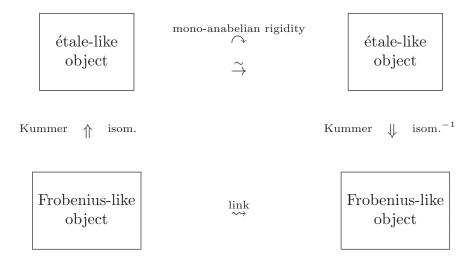

Fig. 2.1: Mono-anabelian transport

(v) The computational technique of mono-anabelian transport: The technique discussed in (iii), i.e., of

computing the effect on positive mass Frobenius-like objects of the links, or "changes of coordinates", under consideration, by first applying some sort of Kummer isomorphism to pass from Frobenius-like to corresponding étale-like objects, then applying some sort of anabelian construction algorithm or rigidity property, and finally applying a suitable inverse Kummer isomorphism to pass from étale-like to corresponding Frobenius-like objects

will be referred to as the technique of mono-anabelian transport [cf. Fig. 2.1] above. In some sense, the most fundamental prototype for this technique is the situation described in Example 2.6.1, (iii) [cf. also the discussion of Example 2.6.1, (iv), (b)]. Here, the term "mono-anabelian" [cf. the discussion of [AbsTopIII], §12] refers to the fact that the algorithm under consideration is an algorithm whose input data [typically] consists only of an abstract profinite group [i.e., that "just happens" to be isomorphic to a Galois group or étale fundamental group that arises from scheme theory!]. This term is used to distinguish from fully faithfulness results [i.e., to the effect that one has a natural bijection between certain types of morphisms of schemes and certain types of morphisms of profinite groups] of the sort that appear in various anabelian conjectures of Grothendieck. Such fully faithfulness results are referred to as "bi-anabelian".

- (vi) Kummer-detachment indeterminacies versus étale-transport indeterminacies: The first step that occurs in the procedure for mono-anabelian transport [cf. the discussion of (v)] is the passage, via some sort of Kummer isomorphism, from Frobenius-like objects to corresponding étale-like objects. This first step is referred to as the Kummer-detachment. The indeterminacies that arise during this first step are referred to as Kummer-detachment indeterminacies [cf. [IUTchIII], Remark 1.5.4]. Such Kummer-detachment indeterminacies typically involve indeterminacies in the cyclotomic rigidity isomorphism that is applied, i.e., as in the situation discussed in Example 2.6.1, (iv), (b). On the other hand, in general, more complicated Kummer-detachment indeterminacies [i.e., that are not directly related to cyclotomic rigidity isomorphisms can occur. By contrast, the indeterminacies that occur as a result of the fact that the étale-like structures under consideration may only be regarded as being known up to an *indeterminate* isomorphism [cf. the discussion of (iii), as well as of §2.10 below] are referred to as étale-transport indeterminacies [cf. [IUTchIII], Remark 1.5.4].
- (vii) Arithmetic holomorphic structures versus mono-analytic struc-A ring may be regarded as consisting of "two combinatorial dimensions" — namely, the underlying additive and multiplicative structures of the ring — which are **intertwined** with one another in a rather complicated fashion [cf. the discussion of [AbsTopIII], §I3; [AbsTopIII], Remark 5.6.1]. In inter-universal Teichmüller theory, one is interested in **dismantling** this complicated intertwining structure by considering the underlying additive and multiplicative monoids associated to a ring separately. In this context, the ring structure, as well as other structures such as étale fundamental groups that are sufficiently rigid as to allow the algorithmic reconstruction of the ring structure, are referred to as arithmetic holomorphic structures. By contrast, structures that arise from dismantling the complicated intertwining inherent in a ring structure are referred to as monoanalytic — a term which may be thought of as a sort of arithmetic analogue of the notion of an underlying real analytic structure in the context of complex holomorphic structures. From this point of view, the approach of Example 2.6.1, (ii), involving the reciprocity map of class field theory depends on the arithmetic **holomorphic structure** [i.e., the ring structure] of the field K in a quite essential and complicated way. By contrast, the **Kummer-theoretic** approach of Example 2.6.1, (iii), only depends on the mono-analytic structure constituted by the underlying multiplicative monoid of the field K, together with the cyclotomic rigidity isomorphism λ . Thus, although λ depends on the ring structure of the field K, the Kummer-theoretic approach of Example 2.6.1, (iii), has the advantage, from the point of view of dismantling the arithmetic holomorphic structure, of

isolating the dependence of κ on the arithmetic holomorphic structure of the field \widetilde{K} in the "compact form" constituted by the cyclotomic rigidity

isomorphism λ .

 $\S 2.8$. Remark on the usage of certain terminology: In the context of the discussion of §2.7, we remark that although terms such as "link", "Frobenius-like", "étale-like", "coric", "mono-anabelian transport", "Kummer-detachment", "cyclotomic rigidity isomorphism", "arithmetic holomorphic structure", and "monoanalytic" are

well-defined in the various specific contexts in which they are applied, these terms do **not** admit **general definitions** that are applicable in all contexts.

In this sense, such terms are used in a way that is similar to the way in which terms such as "underlying" or "anabelian" are typically used in mathematical discussions. The term "multiradial", which will be discussed in §3, is also used in this way.

§**2.9**. Mono-anabelian transport and the Kodaira-Spencer morphism: The discussion of §2.6 and §2.7 be summarized as follows: In some sense, the central theme of inter-universal Teichmüller theory is the computation via monoanabelian transport — in the spirit of the discussion of Example 2.6.1, (iv), (b) — of the **discrepancy** between **two** [systems of] **Kummer theories**, that is to say,

of the sort of **indeterminacies** that one must admit in order to render twosystems of Kummer theories compatible — i.e., relative to the various **gluings** constituted by some link [cf. the Frobenius morphism Φ_{η_X} in Example 2.6.1; the discussion of §2.7, (i)] between the two systems of Kummer theories — with simultaneous execution, e.g., when one of the two systems of Kummer theories [cf. the objects in the lower righthand corner of the diagram of §2.6, (iii), and Fig. 2.1] is held fixed.

In this context, it is of interest to observe that this approach of computing degrees of ["positive mass"] Frobenius-like objects by embedding them into rigid étale-like ["zero mass"] containers [cf. the discussion of §2.7, (iii), (v)] is formally similar to the classical definition of the **Kodaira-Spencer morphism** associated to a family of elliptic curves: Indeed, suppose [relative to the terminology of [Semi], §0] that S^{\log} is a *smooth log curve* over $Spec(\mathbb{C})$ [equipped with the trivial log structure], and that $E^{\log} \to S^{\log}$ is a stable log curve of type (1,1) [i.e., in essence, a family of elliptic curves whose origin is regarded as a "marked point", and which is assumed to have stable reduction at the points of degeneration]. Write $\omega_{S^{\log}/\mathbb{C}}$ for the sheaf of relative logarithmic differentials of $S^{\log} \to \operatorname{Spec}(\mathbb{C})$; $(\mathcal{E}, \nabla_{\mathcal{E}} : \mathcal{E} \to \mathcal{E} \otimes_{\mathcal{O}_S} \omega_{S^{\log}/\mathbb{C}})$ for the rank two vector bundle with logarithmic connection on S^{\log} determined by the first logarithmic de Rham cohomology module of $E^{\log} \to S^{\log}$ and the logarithmic Gauss-Manin connection; $\omega_E \subseteq \mathcal{E}$ for the Hodge filtration on \mathcal{E} ; τ_E for the \mathcal{O}_S -dual of ω_E . Thus, we have a natural exact sequence $0 \to \omega_E \to \mathcal{E} \to \tau_E \to 0$. Then the Kodaira-Spencer morphism associated to the family $E^{\log} \to S^{\log}$ may be defined as the composite of morphisms in the diagram

$$\begin{array}{ccc} \mathcal{E} & \xrightarrow{\nabla \varepsilon} & \mathcal{E} \otimes_{\mathcal{O}_S} \omega_{S^{\log}/\mathbb{C}} \\ \uparrow & & \downarrow \\ \omega_E & \tau_E \otimes_{\mathcal{O}_S} \omega_{S^{\log}/\mathbb{C}} \end{array}$$

— where the left-hand vertical arrow is the natural inclusion, and the right-hand vertical arrow is the natural surjection. The three arrows in this diagram may be regarded as corresponding to the three arrows in analogous positions in the diagrams of Example 2.6.1, (iii), and Fig. 2.1. That is to say, this diagram may be understood as a computation of the degree $\deg(-)$ of the "positive mass" Frobenius-like object ω_E that yields an inequality $\deg(\omega_E) \leq \deg(\omega_{S^{\log}/\mathbb{C}}) - \deg(\omega_E)$, i.e.,

$$2 \cdot \deg(\omega_E) \leq \deg(\omega_{S^{\log}/\mathbb{C}})$$

via a comparison of "alien copies" of the "positive mass" Frobenius-like object ω_E that lie on opposite sides of the "link" constituted by a deformation of the moduli/holomorphic structure of the family of elliptic curves under consideration. This comparison is performed by relating these Frobenius-like objects ω_E [or its dual] on either side of the deformation by means of the "zero mass" étale-like object $(\mathcal{E}, \nabla_{\mathcal{E}})$, i.e., which may be thought of as a local system on the open subscheme $U_S \subseteq S$ of the underlying scheme S of S^{\log} where the log structure of S^{\log} is trivial. The tensor product with $\omega_{S^{\log}/\mathbb{C}}$ — and the resulting appearance of the bound $\deg(\omega_{S^{\log}/\mathbb{C}})$ in the above inequality — may be understood as the indeterminacy that one must admit in order to achieve this comparison.

§2.10. Inter-universality: changes of universe as changes of coordinates: One fundamental aspect of the links [cf. the discussion of §2.7, (i)] — namely, the Θ-link and log-link — that occur in inter-universal Teichmüller theory is their incompatibility with the ring structures of the rings and schemes that appear in their domains and codomains. In particular, when one considers the result of transporting an étale-like structure such as a Galois group [or étale fundamental group] across such a link [cf. the discussion of §2.7, (iii)], one must abandon the interpretation of such a Galois group as a group of automorphisms of some ring [or field] structure [cf. [AbsTopIII], Remark 3.7.7, (i); [IUTchIV], Remarks 3.6.2, 3.6.3], i.e., one must regard such a Galois group as an abstract topological group that is not equipped with any of the "labelling structures" that arise from the relationship between the Galois group and various scheme-theoretic objects. It is precisely this state of affairs that results in

the quite *central role* played in inter-universal Teichmüller theory by results in [mono-]anabelian geometry, i.e., by results concerned with reconstructing various scheme-theoretic structures from an abstract topological group that "just happens" to arise from scheme theory as a Galois group/étale fundamental group.

In this context, we remark that it is also this state of affairs that gave rise to the term "inter-universal": That is to say, the notion of a "universe", as well as the use of multiple universes within the discussion of a single set-up in arithmetic geometry, already occurs in the mathematics of the 1960's, i.e., in the mathematics of Galois categories and étale topoi associated to schemes. On the other hand, in this mathematics of the Grothendieck school, typically one only considers relationships between universes — i.e., between labelling apparatuses for sets — that are induced by morphisms of schemes, i.e., in essence by ring homomorphisms. The most typical example of this sort of situation is the functor between Galois categories of étale coverings induced by a morphism of connected schemes. By contrast, the links that

occur in inter-universal Teichmüller theory are constructed by *partially dismantling* the ring structures of the rings in their domains and codomains [cf. the discussion of §2.7, (vii)], hence necessarily result in

much more complicated relationships between the universes — i.e., between the labelling apparatuses for sets — that are adopted in the Galois categories that occur in the domains and codomains of these links, i.e., relationships that do not respect the various labelling apparatuses for sets that arise from correspondences between the Galois groups that appear and the respective ring/scheme theories that occur in the domains and codomains of the links.

That is to say, it is precisely this sort of situation that is referred to by the term "inter-universal". Put another way,

a **change of universe** may be thought of [cf. the discussion of §2.7, (i)] as a sort of **abstract/combinatorial/arithmetic** version of the classical notion of a "**change of coordinates**".

In this context, it is perhaps of interest to observe that, from a purely classical point of view, the notion of a [physical] "universe" was typically visualized as a copy of Euclidean three-space. Thus, from this classical point of view,

a "change of universe" literally corresponds to a "classical change of the coodinate system — i.e., the labelling apparatus — applied to label points in Euclidean three-space"!

Indeed, from an *even more elementary* point of view, perhaps the simplest example of the essential phenomenon under consideration here is the following **purely combinatorial phenomenon**: Consider the **string of symbols**

010

— i.e., where "0" and "1" are to be understood as formal symbols. Then, from the point of view of the length two *substring* 01 on the *left*, the digit "1" of this substring may be specified by means of its "coordinate relative to this substring", namely, as the *symbol to the far right* of the substring 01. In a similar vein, from the point of view of the length two *substring* 10 on the *right*, the digit "1" of this substring may be specified by means of its "coordinate relative to this substring", namely, as the *symbol to the far left* of the substring 10. On the other hand,

neither of these specifications via "substring-based coordinate systems" is meaningful to the opposite length two substring; that is to say, only the solitary abstract symbol "1" is simultaneously meaningful, as a device for specifying the digit of interest, relative to both of the "substring-based coordinate systems".

Finally, in passing, we note that this discussion applies, albeit in perhaps a somewhat trivial way, to the isomorphism of Galois groups $\Psi_{\eta_X}: G_K \xrightarrow{\sim} G_K$ induced by the Frobenius morphism Φ_{η_X} in Example 2.6.1, (i): That is to say, from the point of view of classical ring theory, this isomorphism of Galois groups is easily seen to coincide with the identity automorphism of G_K . On the other hand, if one takes the point of view that elements of various subquotients of G_K are equipped with *labels* that arise from the isomorphisms ρ or κ of Example 2.6.1, (ii), (iii), i.e., from the *reciprocity* map of *class field theory* or *Kummer theory*, then one must regard such labelling apparatuses are being **incompatible** with the **Frobenius morphism** Φ_{η_X} . Thus, from this point of view, the isomorphism Φ_{η_X} must be regarded as a "**mysterious**, **indeterminate isomorphism**" [cf. the discussion of §2.7, (iii)].

§2.11. The two underlying combinatorial dimensions of a ring: Before proceeding, we pause to examine in more detail the two underlying combinatorial dimensions of a ring discussed in §2.7, (vii) [cf. also [AbsTopIII], §I3]. One way of expressing these two underlying combinatorial dimensions of a ring — i.e., constituted by addition and multiplication — is by means of semi-direct product groups such as

$$\mathbb{Z}_l \rtimes \mathbb{Z}_l^{\times}$$
 or $\mathbb{F}_l \rtimes \mathbb{F}_l^{\times}$

— where l is a prime number; \mathbb{Z}_l denotes, by abuse of notation, the underlying additive profinite group of the ring " \mathbb{Z}_l " of l-adic integers; \mathbb{Z}_l^{\times} denotes the multiplicative profinite group of invertible l-adic integers; \mathbb{F}_l , by abuse of notation, denotes the underlying additive group of the finite field " \mathbb{F}_l " of l elements; \mathbb{F}_l^{\times} denotes the multiplicative group of the field \mathbb{F}_l ; \mathbb{Z}_l^{\times} , \mathbb{F}_l^{\times} act on \mathbb{Z}_l , \mathbb{F}_l via the ring structure of \mathbb{Z}_l , \mathbb{F}_l . Here, we note that both [the rings] \mathbb{Z}_l and \mathbb{F}_l are closely related to the fundamental ring \mathbb{Z} . Indeed, \mathbb{Z} may be regarded as a dense subring of \mathbb{Z}_l , while \mathbb{F}_l may be regarded as a "good finite discrete approximation" of \mathbb{Z}_l whenever l is "large" by comparison to the numbers of interest. Note, moreover, that if $G_k \stackrel{\text{def}}{=} \operatorname{Gal}(\overline{k}/k)$ is the absolute Galois group of a mixed-characteristic local field [i.e., "MLF"] k of residue characteristic $p \neq l$ for which \overline{k} is an algebraic closure, then the maximal tame quotient $G_k \to G_k^{\text{tm}}$ is isomorphic to some open subgroup of the closed subgroup of the direct product

$$\prod_{l \neq p} \mathbb{Z}_l \times \mathbb{Z}_l^{\times}$$

given by the inverse image via the quotient

$$\left(\prod_{l\neq p} \mathbb{Z}_l \times \mathbb{Z}_l^{\times} \longrightarrow \right) \prod_{l\neq p} \mathbb{Z}_l^{\times}$$

of the closed subgroup topologically generated by the image of p [cf. [NSW], Proposition 7.5.1]. In particular, from a purely cohomological point of view, the two combinatorial dimensions " \mathbb{Z}_l " and " \mathbb{Z}_l^{\times} " of the semi-direct product group $\mathbb{Z}_l \times \mathbb{Z}_l^{\times}$ — i.e., which correspond to the additive and multiplicative structures of the ring \mathbb{Z}_l — may be thought of as corresponding directly to the two l-cohomological dimensions [cf. [NSW], Theorem 7.1.8, (i)] of the profinite group G_k^{tm} or, equivalently [since $l \neq p$], of the profinite group G_k . This suggests the point of view that the "restriction to l" should not be regarded as essential, i.e., that one should regard

the two underlying combinatorial dimensions of the ring k as corresponding to the two cohomological dimensions of its absolute Galois group G_k ,

and indeed, more generally, since the two cohomological dimensions of the absolute Galois G_F of a [say, for simplicity, totally imaginary] number field F [cf. [NSW], Proposition 8.3.17] may be thought of, via the well-known classical theory of the *Brauer group*, as *globalizations* [cf. [NSW], Corollary 8.1.16; [NSW], Theorem 8.1.17] of the two cohomological dimensions of the absolute Galois groups of its [say, for simplicity, *nonarchimedean*] *localizations*, that one should regard

the two underlying combinatorial dimensions of a [totally imaginary] number field F as corresponding to the two cohomological dimensions of its absolute Galois group G_F .

Moreover, in the case of the local field k, the two cohomological dimensions of G_k may be thought of as arising [cf., e.g., the proof of [NSW], Theorem 7.1.8, (i)] from the one cohomological dimension of the maximal unramified quotient $G_k oup G_k^{\text{unr}}$ ($\cong \mathbb{Z}$) and the one cohomological dimension of the inertia subgroup $I_k \stackrel{\text{def}}{=} \operatorname{Ker}(G_k oup G_k^{\text{unr}})$. Since I_k and G_k^{unr} may be thought of as corresponding, via local class field theory [cf. [NSW], Theorem 7.2.3], or, alternatively [i.e., "dually" — cf. [NSW], Theorem 7.2.6], via **Kummer theory**, to the subquotients of the multiplicative group k^{\times} associated to k given by the unit group \mathcal{O}_k^{\times} and the value group $k^{\times}/\mathcal{O}_k^{\times}$ of k, we conclude that it is natural to regard

the two underlying combinatorial dimensions of the ring k, or, alternatively, the two cohomological dimensions of its absolute Galois group G_k , as corresponding to the natural exact sequence

$$1 \rightarrow \mathcal{O}_k^{\times} \rightarrow k^{\times} \rightarrow k^{\times}/\mathcal{O}_k^{\times} \rightarrow 1$$

— i.e., to the [non-split!] "decomposition" of k^{\times} into its **unit group** \mathcal{O}_k^{\times} and **value group** $k^{\times}/\mathcal{O}_k^{\times}$.

This situation is reminiscent of the [split!] decomposition of the multiplicative topological group \mathbb{C}^{\times} associated to the field of **complex numbers**, i.e., which is equipped with a natural decomposition

$$\mathbb{C}^{\times} \stackrel{\sim}{\to} \mathbb{S}^1 \times \mathbb{R}_{>0}$$

as a direct product of its **unit group** \mathbb{S}^1 and **value group** $\mathbb{R}_{>0}$ [i.e., the multiplicative group of positive real numbers].

§2.12. Mono-anabelian transport for mixed-characteristic local fields: The discussion of the two underlying combinatorial dimensions of a ring in §2.11—especially, in the case of an MLF "k"—leads naturally, from the point of view of the analogy discussed in §2.2, §2.3, §2.4, §2.5, and §2.7 with the classical theory of §1.4 and §1.5, to consideration of the following examples, which may be thought of as arithmetic analogues of the discussion in Step 7 of §1.5 of the effect of upper triangular linear transformations and rotations on "local masses". As one might expect from the discussion of §2.7, Kummer theory—i.e., applied to relate Frobenius-like structures to their étale-like counterparts—and cyclotomic rigidity isomorphisms play a central role in these examples. In the

following examples, we use the notation of $\S 2.11$ for "k" and various objects related to k; also, we shall write

$$(\mathcal{O}_k^{\times} \subseteq) \qquad \mathcal{O}_k^{\rhd} \qquad (\subseteq k^{\times})$$

for the topological multiplicative monoid of nonzero integral elements of k,

$$\mu_k \subseteq \mathcal{O}_k^{\triangleright}$$

for the topological module of torsion elements of $\mathcal{O}_k^{\triangleright}$, and

$$\rho_k : k^{\times} \hookrightarrow (k^{\times})^{\wedge} \stackrel{\sim}{\to} G_k^{\mathrm{ab}}$$

for the composite of the *embedding* of k^{\times} into its profinite completion $(k^{\times})^{\wedge}$ with the *natural isomorphism* [i.e., which arises from *local class field theory*] of $(k^{\times})^{\wedge}$ with the *abelianization* G_k^{ab} of G_k . Here, we recall, from local class field theory, that ρ_k is *functorial* with respect to passage to *finite subextensions* of k in \overline{k} and the *Verlagerung* homomorphism between abelianizations of open subgroups of G_k . Also, we recall [cf., e.g., [AbsAnab], Proposition 1.2.1, (iii), (iv)] that the *images* $\rho_k(\mu_k) \subseteq \rho_k(\mathcal{O}_k^{\triangleright}) \subseteq \rho_k(k^{\times}) \subseteq G_k^{ab}$ of μ_k , $\mathcal{O}_k^{\triangleright}$, and k^{\times} via ρ_k may be **constructed group-theoretically** from the topological group G_k . The notation introduced so far for various objects related to k will also be applied to finite subextensions of k in \overline{k} , as well as [i.e., by passing to suitable *inductive limits*] to \overline{k} itself. In particular, if we write

$$\mu_{\overline{k}}(G_k) \subseteq \mathcal{O}_{\overline{k}}^{\triangleright}(G_k) \subseteq \overline{k}^{\times}(G_k)$$

for the respective *inductive systems* [or, by abuse of notation, when there is no fear of confusion, *inductive limits*], relative to the *Verlagerung* homomorphism between abelianizations of open subgroups of G_k , of the [group-theoretically constructible!] submonoids $\rho_{k'}(\mu_{k'}) \subseteq \rho_{k'}(\mathcal{O}_{k'}^{\triangleright}) \subseteq \rho_{k'}((k')^{\times}) \subseteq G_{k'}^{ab}$ associated to the various open subgroups $G_{k'} \subseteq G_k$ [i.e., where k' ranges over the finite subextensions of k in \overline{k}], then the various $\rho_{k'}$ determine natural isomorphisms

$$\rho_{\boldsymbol{\mu}_{\overline{k}}}:\boldsymbol{\mu}_{\overline{k}} \overset{\sim}{\to} \boldsymbol{\mu}_{\overline{k}}(G_k), \qquad \rho_{\mathcal{O}_{\overline{k}}^{\triangleright}}:\mathcal{O}_{\overline{k}}^{\triangleright} \overset{\sim}{\to} \mathcal{O}_{\overline{k}}^{\triangleright}(G_k), \qquad \rho_{\overline{k}^{\times}}:\overline{k}^{\times} \overset{\sim}{\to} \overline{k}^{\times}(G_k)$$

of [multiplicative] G_k -modules. In the following, we shall also use the notation $\boldsymbol{\mu}_{\overline{k}}^{\widehat{\mathbb{Z}}} \stackrel{\text{def}}{=} \operatorname{Hom}(\mathbb{Q}/\mathbb{Z}, \boldsymbol{\mu}_{\overline{k}})$ and $\boldsymbol{\mu}_{\overline{k}}^{\widehat{\mathbb{Z}}}(G_k) \stackrel{\text{def}}{=} \operatorname{Hom}(\mathbb{Q}/\mathbb{Z}, \boldsymbol{\mu}_{\overline{k}}(G_k))$.

Example 2.12.1: Nonarchimedean multiplicative monoids of local integers.

(i) In the following, we wish to regard the pair " $G_k \curvearrowright \mathcal{O}_{\overline{k}}^{\trianglerighteq}$ " as an abstract ind-topological monoid " $\mathcal{O}_{\overline{k}}^{\trianglerighteq}$ " [i.e., inductive system of topological monoids] equipped with a continuous action by an abstract topological group " G_k ". Thus, for instance, we may think of \overline{k}^{\times} as the groupification $(\mathcal{O}_{\overline{k}}^{\trianglerighteq})^{\operatorname{gp}}$ of the monoid $\mathcal{O}_{\overline{k}}^{\trianglerighteq}$, of $\mu_{\overline{k}}$ as the subgroup of torsion elements of monoid $\mathcal{O}_{\overline{k}}^{\trianglerighteq}$, and of $\mathcal{O}_k^{\trianglerighteq} \subseteq k^{\times}$ as the result of considering the G_k -invariants $(\mathcal{O}_{\overline{k}}^{\trianglerighteq})^{G_k} \subseteq (\overline{k}^{\times})^{G_k}$ of the inclusion $\mathcal{O}_{\overline{k}}^{\trianglerighteq} \subseteq \overline{k}^{\times}$.

Observe that, by considering the action of G_k on the various N-th roots, for N a positive integer, of elements of k^{\times} , we obtain a natural **Kummer map**

$$\kappa_k : k^{\times} \hookrightarrow H^1(G_k, \boldsymbol{\mu}_{\overline{k}}^{\widehat{\mathbb{Z}}})$$

— which may be *composed* with the natural isomorphism $\rho_{\mu_{\overline{k}}}$ to obtain a *natural* embedding

$$\kappa_k^{\mathrm{Gal}}: k^{\times} \hookrightarrow H^1(G_k, \boldsymbol{\mu}_{\overline{k}}^{\widehat{\mathbb{Z}}}(G_k))$$

— where we note that the cohomology module in the codomain of this embedding may be **constructed group-theoretically** from the abstract topological group " G_k ". On the other hand, it follows immediately from the definitions that κ_k may be **constructed functorially** from the abstract ind-topological monoid with continuous topological group action " $G_k \wedge \mathcal{O}_{\overline{k}}^{\triangleright}$ ".

(ii) In fact,

 $\rho_{\mu_{\overline{k}}}$ may also be **constructed functorially** from the abstract ind-topological monoid with continuous topological group action " $G_k \curvearrowright \mathcal{O}_{\overline{k}}^{\triangleright}$ ".

Indeed, this follows formally from the fact that

there exists a canonical isomorphism $\mathbb{Q}/\mathbb{Z} \stackrel{\sim}{\to} H^2(G_k, \mu_{\overline{k}})$ that may be constructed functorially from this data " $G_k \curvearrowright \mathcal{O}_{\overline{k}}^{\triangleright}$ ".

— i.e., by applying this functorial construction to both the data " $G_k \curvearrowright \mathcal{O}_{\overline{k}}^{\triangleright}$ " and the data " $G_k \curvearrowright \mathcal{O}_{\overline{k}}^{\triangleright}(G_k)$ " and then observing that $\rho_{\mu_{\overline{k}}}$ may be characterized as the unique isomorphism $\mu_{\overline{k}} \stackrel{\sim}{\to} \mu_{\overline{k}}(G_k)$ that is compatible with the isomorphisms $\mathbb{Q}/\mathbb{Z} \xrightarrow{\sim} H^2(G_k, \mu_{\overline{k}})$ and $\mathbb{Q}/\mathbb{Z} \xrightarrow{\sim} H^2(G_k, \mu_{\overline{k}}(G_k))$. To construct this canonical isomorphism [cf., e.g., the proof of [AbsAnab], Proposition 1.2.1, (vii); the statement and proof of [FrdII], Theorem 2.4, (ii); the statement of [AbsTopIII], Corollary 1.10, (i), (a); the statement of [AbsTopIII], Proposition 3.2, (i), for more details], we first observe that since $\overline{k}^{\times}/\mu_{\overline{k}}$ is a \mathbb{Q} -vector space, it follows that we have natural isomorphisms $H^2(G_k, \mu_{\overline{k}}) \stackrel{\sim}{\to} H^2(G_k, \overline{k}^{\times}), H^2(I_k, \mu_{\overline{k}}) \stackrel{\sim}{\to} H^2(I_k, \overline{k}^{\times}).$ Since, moreover, the inertia subgroup $I_k \subseteq G_k$ is of cohomological dimension 1 [cf. the discussion of §2.11], we conclude that $H^2(I_k, \overline{k}^{\times}) \stackrel{\sim}{\to} H^2(I_k, \mu_{\overline{k}}) = 0$. Next, let us recall that, by elementary Galois theory [i.e., "Hilbert's Theorem 90"], one knows that $H^1(I_k, \overline{k}^{\times}) = 0$. Thus, we conclude from the *Leray-Serre spectral sequence* associated to the extension $1 \to I_k \to G_k \to G_k^{\text{unr}} \to 1$ that, if we write $k^{\mathrm{unr}} \subseteq \overline{k}$ for the subfield of I_k -invariants of \overline{k} , then we have a natural isomor $phism\ H^2(G_k, \overline{k}^{\times}) \stackrel{\sim}{\to} H^2(G_k^{\text{unr}}, (k^{\text{unr}})^{\times}).$ On the other hand, the valuation map on $(k^{\mathrm{unr}})^{\times}$ determines an isomorphism $H^2(G_k^{\mathrm{unr}},(k^{\mathrm{unr}})^{\times}) \stackrel{\sim}{\to} H^2(G_k^{\mathrm{unr}},\mathbb{Z})$ [where again we apply "Hilbert's Theorem 90", this time to the residue field of k]. Moreover, by applying the isomorphism determined by the Frobenius element $G_k^{\text{unr}} \stackrel{\sim}{\to} \widehat{\mathbb{Z}}$ [which is group-theoretically constructible — cf. [AbsAnab], Proposition 1.2.1, (iv)], together with the long exact sequence in Galois cohomology associated to the short exact sequence $0 \to \mathbb{Z} \to \mathbb{Q} \to \mathbb{Q}/\mathbb{Z} \to 0$ [and the fact that \mathbb{Q} is a \mathbb{Q} -vector space!], we ob- $\text{tain a } natural \ isomorphism \ H^2(G_k^{\text{unr}},\mathbb{Z}) \overset{\sim}{\to} H^1(G_k^{\text{unr}},\mathbb{Q}/\mathbb{Z}) \overset{\sim}{\to} \text{Hom}(\widehat{\mathbb{Z}},\mathbb{Q}/\mathbb{Z}) = \mathbb{Q}/\mathbb{Z}.$ Thus, by taking the *inverse* of the *composite* of the various natural isomorphisms

constructed so far [solely from the data " $G_k \curvearrowright \mathcal{O}_{\overline{k}}^{\trianglerighteq}$ "!], we obtain the desired canonical isomorphism $\mathbb{Q}/\mathbb{Z} \xrightarrow{\sim} H^2(G_k, \mu_{\overline{k}})$.

(iii) The functorial construction given in (ii) — i.e., via well-known elementary techniques involving **Brauer groups** of the sort that appear in **local class field theory** — of the **cyclotomic rigidity isomorphism** $\rho_{\mu_{\overline{k}}}$ from the data " $G_k \curvearrowright \mathcal{O}_{\overline{k}}^{\trianglerighteq}$ " is perhaps the most fundamental case — at least in the context of the arithmetic of NF's and MLF's — of the phenomenon of **cyclotomic rigidity**. One formal consequence of the discussion of (i), (ii) is the fact that the operation of passing from the data " $G_k \curvearrowright \mathcal{O}_{\overline{k}}^{\trianglerighteq}$ " to the data " G_k " is fully faithful, i.e., one has a natural bijection

$$\operatorname{Aut}(G_k \curvearrowright \mathcal{O}_{\overline{k}}^{\triangleright}) \stackrel{\sim}{\to} \operatorname{Aut}(G_k)$$

— where the first "Aut(-)" denotes automorphisms of the data " $G_k opin \mathcal{O}_{\overline{k}}^{\triangleright}$ " consisting of an abstract ind-topological monoid with continuous topological group action; the second "Aut(-)" denotes automorphisms of the data " G_k " consisting of an abstract topological group [cf. [AbsTopIII], Proposition 3.2, (iv)]. Indeed, surjectivity follows formally from the functorial construction of the data " $G_k opin \mathcal{O}_{\overline{k}}^{\triangleright}(G_k)$ " from the abstract topological group G_k [cf. the discussion at the beginning of the present §2.12]; injectivity follows formally from the fact that, as a consequence of the cyclotomic rigidity discussed in (ii), one has a functorial construction from the data " $G_k opin \mathcal{O}_{\overline{k}}^{\triangleright}$ " of the **embedding** $\kappa_k^{\text{Gal}}: k^{\times} \hookrightarrow H^1(G_k, \mu_{\overline{k}}^{\widehat{\mathbb{Z}}}(G_k))$ [in fact applied in the case where "k" is replaced by arbitrary finite subextensions of k in \overline{k}] into the **container** $H^1(G_k, \mu_{\overline{k}}^{\widehat{\mathbb{Z}}}(G_k))$ [which may be constructed solely from the abstract topological group G_k !]. Note that this situation may also be understood in terms of the general framework of **mono-anabelian transport** discussed in §2.7, (v) [cf. also Example 2.6.1, (iii), (iv)], by considering the commutative diagram

$$H^{1}(G_{k}, \boldsymbol{\mu}_{\overline{k}}^{\widehat{\mathbb{Z}}}(G_{k})) \stackrel{\sim}{\longrightarrow} H^{1}(G_{k}, \boldsymbol{\mu}_{\overline{k}}^{\widehat{\mathbb{Z}}}(G_{k}))$$

$$\uparrow^{\kappa_{k}^{\operatorname{Gal}}|_{\mathcal{O}_{k}^{\triangleright}}} \stackrel{\sim}{\frown} \uparrow^{\kappa_{k}^{\operatorname{Gal}}|_{\mathcal{O}_{k}^{\triangleright}}}$$

$$\mathcal{O}_{k}^{\triangleright} \stackrel{\sim}{\longrightarrow} \mathcal{O}_{k}^{\triangleright}$$

— where the horizontal arrows are induced by some given automorphism of the data " $G_k o \mathcal{O}_k^{\triangleright}$ "; the vertical arrows serve to embed the **Frobenius-like** data " $\mathcal{O}_k^{\triangleright}$ " into the **étale-like container** $H^1(G_k, \boldsymbol{\mu}_{\overline{k}}^{\widehat{\mathbb{Z}}}(G_k))$. Finally, we observe that the *cyclotomic rigidity* discussed in (ii) may be understood, relative to the exact sequence

$$1 \ \to \ \mathcal{O}_{\overline{k}}^{\times} \ \to \ \overline{k}^{\times} \ \to \ \overline{k}^{\times} / \mathcal{O}_{\overline{k}}^{\times} \ (\cong \mathbb{Q}) \ \to \ 1$$

— which, as was discussed in the final portion of §2.11, may be thought of as corresponding to the two underlying combinatorial dimensions of the ring \overline{k} — as revolving around the **rigidity** of the two fundamental subquotients $\mu_{\overline{k}} \subseteq \overline{k}^{\times}$ and $\overline{k}^{\times} \to \overline{k}^{\times}/\mathcal{O}_{\overline{k}}^{\times}$ of \overline{k}^{\times} . When viewed in this light, the discussion of the present Example 2.12.1 may be thought of, relative to the analogy discussed in §2.2, §2.3, §2.4, §2.5, and §2.7 with the classical theory of §1.4 and §1.5, as corresponding to the

discussion of the effect on "local masses" of the unipotent linear transformations that appeared in the discussion of Step 7 of §1.5.

(iv) At this point, it is perhaps of interest to observe that there is an alternative approach to constructing the cyclotomic rigidity isomorphism $\rho_{\mu_{\overline{k}}}$. That is to say, instead of reasoning as in (ii), one may reason as follows. First, we observe that, by applying the functorial construction of (ii) in the case of the data " $G_k \curvearrowright \mathcal{O}_{\overline{k}}^{\triangleright}(G_k)$ ", one obtains a canonical isomorphism $\mathbb{Q}/\mathbb{Z} \xrightarrow{\sim} H^2(G_k, \mu_{\overline{k}}^{\widehat{\mathbb{Z}}}(G_k))$. Since the cup product in group cohomology, together with this canonical isomorphism, determines a perfect duality [cf. [NSW], Theorem 7.2.6], one thus obtains a natural isomorphism $G_k^{\mathrm{ab}} \xrightarrow{\sim} H^1(G_k, \mu_{\overline{k}}^{\widehat{\mathbb{Z}}}(G_k))$. Write

$$\mathcal{O}_k^{\triangleright}(G_k)^{\mathrm{Kum}} \subseteq H^1(G_k, \boldsymbol{\mu}_{\overline{k}}^{\widehat{\mathbb{Z}}}(G_k))$$

for the image via this natural isomorphism of $\mathcal{O}_k^{\triangleright}(G_k) \subseteq G_k^{\mathrm{ab}}$ [i.e., the submodule of G_k -invariants of $\mathcal{O}_k^{\triangleright}(G_k)$]. Thus, $\mathcal{O}_k^{\triangleright}(G_k)^{\mathrm{Kum}}$ may be constructed group-theoretically from the abstract topological group G_k . Next, let us recall the elementary fact that, relative to the natural inclusion $\mathbb{Q} \hookrightarrow \widehat{\mathbb{Z}} \otimes \mathbb{Q}$, we have an equality

$$\mathbb{Q}_{>0} \bigcap \widehat{\mathbb{Z}}^{\times} = \{1\}$$

— where $\mathbb{Q}_{>0} \subseteq \mathbb{Q}$ denotes the multiplicative monoid of positive rational numbers. Now let us observe that it follows formally from this elementary fact — for instance, by considering the quotient $\mathcal{O}_k^{\triangleright}(G_k) \twoheadrightarrow \mathcal{O}_k^{\triangleright}(G_k)/\mathcal{O}_k^{\times}(G_k) \ (\cong \mathbb{N})$ — that the only element $\in \widehat{\mathbb{Z}}^{\times}$ that, relative to the natural action of $\widehat{\mathbb{Z}}^{\times}$ on $H^1(G_k, \mu_{\overline{k}}^{\widehat{\mathbb{Z}}}(G_k))$ [i.e., induced by the natural action of $\widehat{\mathbb{Z}}^{\times}$ on $\mu_{\overline{k}}(G_k)$], preserves the submonoid $\mathcal{O}_k^{\triangleright}(G_k)$ is the identity element $1 \in \widehat{\mathbb{Z}}^{\times}$. In particular, it follows that

the cyclotomic rigidity isomorphism $\rho_{\boldsymbol{\mu}_{\overline{k}}}$ may be *characterized* as the *unique* isomorphism $\boldsymbol{\mu}_{\overline{k}} \overset{\sim}{\to} \boldsymbol{\mu}_{\overline{k}}(G_k)$ that is *compatible* with the submonoids $\kappa_k(\mathcal{O}_k^{\triangleright}) \subseteq H^1(G_k, \boldsymbol{\mu}_{\overline{k}}^{\widehat{\mathbb{Z}}})$ and $\mathcal{O}_k^{\triangleright}(G_k)^{\operatorname{Kum}} \subseteq H^1(G_k, \boldsymbol{\mu}_{\overline{k}}^{\widehat{\mathbb{Z}}}(G_k))$.

This characterization thus yields an alternative approach to the characterization of the cyclotomic rigidity isomorphism $\rho_{\mu_{\overline{k}}}$ given in (ii) [cf. the discussion of [IUTchIII], Remark 2.3.3, (viii)]. On the other hand, there is a **fundamental difference** between this alternative approach and the approach of (ii): Indeed, one verifies immediately that the approach of (ii) is **compatible** with the **profinite topology** of G_k in the sense that the construction of (ii) may be formulated as the result of applying a suitable limit operation to "finite versions" of this construction of (ii), i.e., versions in which " G_k " is replaced by the quotients of " G_k " by sufficiently small normal open subgroups of " G_k ", and " $\mathcal{O}_{\overline{k}}^{\triangleright}$ " is replaced by the submonoids of invariants with respect to such normal open subgroups. By contrast, the alternative approach just discussed is **fundamentally incompatible** with the profinite topology of G_k in the sense that the crucial fact $\mathbb{Q}_{>0}$ \cap $\widehat{\mathbb{Z}}^{\times} = \{1\}$ — which may be thought of as a sort of **discreteness** property [cf. the discussion of [IUTchIII], Remark 3.12.1, (iii); [IUTchIV], Remark 2.3.3, (ii)] — may only be applied at the level of the full profinite group G_k [i.e., at the level of Kummer

classes with coefficients in some copy of $\widehat{\mathbb{Z}}(1)$], not at the level of finite quotients of G_k [i.e., at the level of Kummer classes with coefficients in some finite quotient of some copy of $\widehat{\mathbb{Z}}(1)$]. Thus, in summary, although this alternative approach has the **disadvantage** of being **incompatible** with the **profinite topology** of G_k , various versions of this approach — i.e., involving constructions that depend, in an essential way, on the crucial fact $\mathbb{Q}_{>0} \cap \widehat{\mathbb{Z}}^{\times} = \{1\}$ — will, nevertheless, play an important role in inter-universal Teichmüller theory [cf. the discussion of Example 2.13.1 below].

<u>Example 2.12.2</u>: Frobenius morphisms on nonarchimedean multiplicative monoids of local integers.

(i) One way to gain a further appreciation of the cyclotomic rigidity phenomenon discussed in Example 2.12.1 is to consider the pair " $G_k \curvearrowright \mathcal{O}_{\overline{k}}^{\times}$ ", which again we regard as consisting of an abstract ind-topological monoid " $\mathcal{O}_{\overline{k}}^{\times}$ " [i.e., inductive system of topological monoids] equipped with a continuous action by an abstract topological group " G_k ". Since $\mathcal{O}_{\overline{k}}^{\times}$ may be thought of as an inductive system/limit of profinite abelian groups, it follows immediately that there is a natural G_k -equivariant action of $\widehat{\mathbb{Z}}^{\times}$ on the data " $G_k \curvearrowright \mathcal{O}_{\overline{k}}^{\times}$ ". Moreover, if α is an arbitrary automorphism of this data " $G_k \curvearrowright \mathcal{O}_{\overline{k}}^{\times}$ " [i.e., regarded as an abstract ind-topological monoid equipped with a continuous action by an abstract topological group], then although it is not necessarily the case that α is compatible with the cyclotomic rigidity isomorphism $\rho_{\mu_{\overline{k}}}: \mu_{\overline{k}} \xrightarrow{\sim} \mu_{\overline{k}}(G_k)$, one verifies immediately [from the fact that, as an abstract abelian group, $\mu_{\overline{k}} \cong \mathbb{Q}/\mathbb{Z}$, together with the elementary fact that $\mathrm{Aut}(\mathbb{Q}/\mathbb{Z}) = \widehat{\mathbb{Z}}^{\times}$] that there always exists a unique element $\lambda \in \widehat{\mathbb{Z}}^{\times}$ such that the automorphism $\lambda \cdot \alpha$ of the data " $G_k \curvearrowright \mathcal{O}_{\overline{k}}^{\times}$ " is compatible with $\rho_{\mu_{\overline{k}}}$. Thus, by arguing as in Example 2.12.1, (iii), one concludes that one has a natural bijection

$$\operatorname{Aut}(G_k \curvearrowright \mathcal{O}_{\overline{k}}^{\times}) \stackrel{\sim}{\to} \widehat{\mathbb{Z}}^{\times} \times \operatorname{Aut}(G_k)$$

— where the first "Aut(-)" denotes automorphisms of the data " $G_k \curvearrowright \mathcal{O}_{\overline{k}}^{\times}$ " consisting of an abstract ind-topological monoid with continuous topological group action; the second "Aut(-)" denotes automorphisms of the data " G_k " consisting of an abstract topological group [cf. [AbsTopIII], Proposition 3.3, (ii); [FrdII], Remark 2.4.2]. Just as in the case of Example 2.12.1, (iii), this situation may also be understood in terms of the general framework of **mono-anabelian transport** discussed in §2.7, (v) [cf. also Example 2.6.1, (iii), (iv)], by considering the commutative diagram

$$H^{1}(G_{k}, \boldsymbol{\mu}_{\overline{k}}^{\widehat{\mathbb{Z}}}(G_{k})) \stackrel{\sim}{\longrightarrow} H^{1}(G_{k}, \boldsymbol{\mu}_{\overline{k}}^{\widehat{\mathbb{Z}}}(G_{k}))$$

$$\uparrow^{\kappa_{k}^{\operatorname{Gal}}|_{\mathcal{O}_{k}^{\times}}} \stackrel{\sim}{\curvearrowright} ? \qquad \uparrow^{\kappa_{k}^{\operatorname{Gal}}|_{\mathcal{O}_{k}^{\times}}}$$

$$\mathcal{O}_{k}^{\times} \stackrel{\sim}{\longrightarrow} \mathcal{O}_{k}^{\times}$$

— where the horizontal arrows are induced by some given automorphism of the data " $G_k \curvearrowright \mathcal{O}_{\overline{k}}^{\times}$ "; the vertical arrows serve to embed the **Frobenius-like** data " \mathcal{O}_k^{\times} " into the **étale-like container** $H^1(G_k, \mu_{\overline{k}}^{\widehat{\mathbb{Z}}}(G_k))$; the diagram commutes [cf. " \curvearrowright ?"] up to the action of a suitable element $\in \widehat{\mathbb{Z}}^{\times}$.

(ii) Let $\pi_k \in \mathcal{O}_k^{\triangleright}$ be a uniformizer of \mathcal{O}_k . Then one sort of intermediate type of data between the data " $G_k \curvearrowright \mathcal{O}_{\overline{k}}^{\times}$ " considered in (i) above and the data " $G_k \curvearrowright \mathcal{O}_{\overline{k}}^{\triangleright}$ " considered in Example 2.12.1 is the data " $G_k \curvearrowright \mathcal{O}_{\overline{k}}^{\times} \cdot \mathcal{O}_k^{\triangleright} \ (\subseteq \mathcal{O}_{\overline{k}}^{\triangleright})$ ", which again we regard as consisting of an abstract ind-topological monoid " $\mathcal{O}_{\overline{k}}^{\times}$ " [i.e., inductive system of topological monoids] equipped with a continuous action by an abstract topological group " G_k ". Here, we observe that $\mathcal{O}_{\overline{k}}^{\times} \cdot \mathcal{O}_k^{\triangleright} = \mathcal{O}_{\overline{k}}^{\times} \cdot \pi_k^{\mathbb{N}}$. Let $\mathbb{Z} \ni N \geq 2$, $\alpha \in \operatorname{Aut}(G_k \curvearrowright \mathcal{O}_{\overline{k}}^{\times})$. Then observe that N, α determine — i.e., in the spirit of the discussion of §2.4 — a sort of **Frobenius morphism** $\phi_{N,\alpha}$

$$\begin{pmatrix} G_k \curvearrowright \mathcal{O}_{\overline{k}}^{\times} \cdot \mathcal{O}_k^{\triangleright} \end{pmatrix} \to \begin{pmatrix} G_k \curvearrowright \mathcal{O}_{\overline{k}}^{\times} \cdot \mathcal{O}_k^{\triangleright} \end{pmatrix} \\
\pi_k \mapsto \pi_k^N$$

that restricts to α on the data " $G_k \curvearrowright \mathcal{O}_{\overline{k}}^{\times}$ ". From the point of view of the general framework of **mono-anabelian transport** discussed in §2.7, (v) [cf. also Example 2.6.1, (iii), (iv)], this sort of Frobenius morphism $\phi_{N,\alpha}$ induces a *commutative diagram*

$$H^{1}(G_{k}, \boldsymbol{\mu}_{\overline{k}}^{\widehat{\mathbb{Z}}}(G_{k})) \stackrel{\sim}{\longrightarrow} H^{1}(G_{k}, \boldsymbol{\mu}_{\overline{k}}^{\widehat{\mathbb{Z}}}(G_{k}))$$

$$\uparrow^{\kappa_{k}^{\operatorname{Gal}}|_{\mathcal{O}_{k}^{\triangleright}}} \qquad \curvearrowright ? \qquad \uparrow^{\kappa_{k}^{\operatorname{Gal}}|_{\mathcal{O}_{k}^{\triangleright}}}$$

$$\mathcal{O}_{k}^{\triangleright} \qquad \longrightarrow \qquad \mathcal{O}_{k}^{\triangleright}$$

where the horizontal arrows are induced by $\phi_{N,\alpha}$; the vertical arrows serve to embed the **Frobenius-like** data " $\mathcal{O}_k^{\triangleright}$ " into the **étale-like container** $H^1(G_k, \boldsymbol{\mu}_{\overline{k}}^{\widehat{\mathbb{Z}}}(G_k))$; the diagram commutes [cf. " \curvearrowright ?"] up to the action of a suitable element $\in \widehat{\mathbb{Z}}^{\times}$ on $\mathcal{O}_k^{\times} \subseteq \mathcal{O}_k^{\triangleright}$ and a suitable element $\in \mathbb{N}$ [namely, $N \in \mathbb{N}$] on $\pi_k^{\mathbb{N}}$. Finally, we observe that the **diagonal** nature of the action of $\phi_{N,\alpha}$ on the **unit group** \mathcal{O}_k^{\times} [via α] and the **value group** $\pi_k^{\mathbb{Z}}$ [by raising to the N-th power] portions of the ind-topological monoid $\mathcal{O}_k^{\times} \cdot \mathcal{O}_k^{\triangleright}$ may be thought of, relative to the analogy discussed in §2.2, §2.3, §2.4, §2.5, and §2.7 with the classical theory of §1.4 and §1.5, as corresponding to the discussion of the effect on "**local masses**" of the **toral dilations** that appeared in the discussion of Step 7 of §1.5.

Example 2.12.3: Nonarchimedean logarithms.

(i) The discussion of various simple cases of mono-anabelian transport in Examples 2.12.1, (iii); 2.12.2, (i), (ii), concentrated on the Kummer-theoretic aspects, i.e., in effect, on the Kummer-detachment indeterminacies [cf. §2.7, (vi)], or lack thereof, of the examples considered. On the other hand, another fundamental aspect of these examples [cf. the natural bijections of Examples 2.12.1, (iii); 2.12.2, (i)] is the étale-transport indeterminacies [cf. §2.7, (vi)] that occur as a result of the well-known

existence of elements $\in \operatorname{Aut}(G_k)$ that do **not** preserve the **ring structure** on [the union with $\{0\}$ of] $\mathcal{O}_{\overline{k}}^{\triangleright}(G_k)$

— cf. [NSW], the Closing Remark preceding Theorem 12.2.7. By contrast, if X is a **hyperbolic curve of strictly Belyi type** [cf. [AbsTopII], Definition 3.5] over

k, and we write Π_X for the *étale fundamental group* of X [for a suitable choice of basepoint], then it follows from the theory of [AbsTopIII], §1 [cf. [AbsTopIII], Theorem 1.9; [AbsTopIII], Remark 1.9.2; [AbsTopIII], Corollary 1.10], that

if one regards G_k as a **quotient** $\Pi_X \to G_k$ of Π_X , then there exists a **functorial algorithm** for reconstructing this quotient $\Pi \to G_k$ of Π_X , together with the **ring structure** on [the union with $\{0\}$ of] $\mathcal{O}_k^{\triangleright}(G_k)$, from the abstract topological group Π_X .

Here, we recall that [it follows immediately from the definitions that] any connected finite étale covering of a **once-punctured elliptic curve** [i.e., an elliptic curve minus the origin] over k that is **defined over an NF** is necessarily of strictly Belyi type.

(ii) Write $(\mathcal{O}_{\overline{k}}^{\times})^{\mathrm{pf}}$ for the *perfection* [cf., e.g., [FrdI], §0] of the ind-topological monoid $\mathcal{O}_{\overline{k}}^{\times}$. Thus, it follows immediately from the elementary theory of p-adic fields [cf., e.g., [Kobl], Chapter IV, §1, §2] that the p-adic logarithm determines a G_k -equivariant bijection

$$\log_{\overline{k}}: (\mathcal{O}_{\overline{k}}^{\times})^{\mathrm{pf}} \stackrel{\sim}{\to} \overline{k}$$

with respect to which the operation of **multiplication**, which we shall often denote by the notation " \boxtimes ", in the domain corresponds to the operation of **addition**, which we shall often denote by the notation " \boxplus ", in the codomain. This bijection fits into a diagram

$$\dots \quad \mathcal{O}_{\overline{k}}^{\trianglerighteq} \quad \supseteq \quad \mathcal{O}_{\overline{k}}^{\times} \quad \twoheadrightarrow \quad (\mathcal{O}_{\overline{k}}^{\times})^{\mathrm{pf}} \quad \stackrel{\sim}{\to} \quad \overline{k} \quad \supseteq \quad \mathcal{O}_{\overline{k}}^{\trianglerighteq} \quad \dots$$

— where the "..." on the left and right denote the result of juxtaposing copies of the portion of the diagram "from $\mathcal{O}_{\overline{k}}^{\triangleright}$ to $\mathcal{O}_{\overline{k}}^{\triangleright}$ ", i.e., copies that are glued together along initial/final instances of " $\mathcal{O}_{\overline{k}}^{\triangleright}$ ". Here, we observe that the various objects that appear in this diagram may be regarded as being equipped with a **natural action** of Π_X [for X as in (i)], which acts via the natural quotient $\Pi_X \twoheadrightarrow G_k$. To keep the notation simple, we shall denote the portion of the diagram "from $\mathcal{O}_{\overline{k}}^{\triangleright}$ to $\mathcal{O}_{\overline{k}}^{\triangleright}$ " by means of the notation $\log : \mathcal{O}_{\overline{k}}^{\triangleright} \to \mathcal{O}_{\overline{k}}^{\triangleright}$. Thus, the diagram of the above display may be written

— i.e., regarded as a sequence of iterates of "log". Here, since the operation "log" [i.e., which, in effect, converts " \boxtimes " into " \boxplus "] is **incompatible** with the **ring structures** on [the union with $\{0\}$ of] the copies of $\mathcal{O}_{\overline{k}}^{\triangleright}$ in the domain and codomain of "log", we observe — in accordance with the discussion of $\S 2.10!$ — that it is natural to regard the various copies of $\mathcal{O}_{\overline{k}}^{\triangleright}$ as being equipped with distinct labels and the isomorphisms " $\stackrel{\sim}{\to}$ " between different copies of Π_X as being **indeterminate isomorphisms** between distinct abstract topological groups. Such diagrams are studied in detail in [AbsTopIII], and, moreover, form the fundamental model for

the log-link of inter-universal Teichmüller theory [cf. §3.3, (ii), (vi), below], which is studied in detail in [IUTchIII].

(iii) It follows from the **mono-anabelian** theory of [AbsTopIII], §1 [cf. [AbsTopIII], Theorem 1.9; [AbsTopIII], Corollary 1.10], that, if we regard G_k as a quotient of Π_X , then the image, which we denote by $\mathcal{O}_k^{\triangleright}(\Pi_X)$ ($\subseteq H^1(G_k, \mu_{\overline{k}}^{\widehat{\mathbb{Z}}}(G_k)$)), of $\mathcal{O}_k^{\triangleright}$ via κ_k^{Gal} [cf. Example 2.12.1, (iii)] may be reconstructed — i.e., as a topological monoid equipped with a ring structure [on its union with $\{0\}$] — from the abstract topological group Π_X . By applying this construction to arbitrary open subgroups of G_k and passing to inductive systems/limits, we thus obtain an indtopological monoid $\mathcal{O}_k^{\triangleright}(\Pi_X)$ equipped with a natural continuous action by Π_X and a ring structure [on its union with $\{0\}$]. Thus, from the point of view of the general framework of **mono-anabelian transport** discussed in §2.7, (v) [cf. also Example 2.6.1, (iii), (iv)], we obtain a diagram

$$\mathcal{O}_{\overline{k}}^{\triangleright}(\Pi_X) \xrightarrow{\sim} \mathcal{O}_{\overline{k}}^{\triangleright}(\Pi_X)$$

$$\dots \qquad \uparrow_{\mathrm{Kum}} \qquad \curvearrowright ? \qquad \uparrow_{\mathrm{Kum}} \qquad \dots$$

$$\mathcal{O}_{\overline{k}}^{\triangleright} \qquad \xrightarrow{\mathfrak{log}} \qquad \mathcal{O}_{\overline{k}}^{\triangleright}$$

— where the upper horizontal arrow is induced by some **indeterminate isomorphism** $\Pi_X \stackrel{\sim}{\to} \Pi_X$ [cf. the discussion of §2.10]; the lower horizontal arrow is the operation "log" discussed in (ii); the vertical arrows are the "Kummer isomorphisms" determined by the various " κ_k^{Gal} " associated to open subgroups of G_k ; the "..." denote iterates of the square surrounding the " \curvearrowright ?". Thus, the vertical arrows of this diagram relate the various copies of **Frobenius-like** data $\mathcal{O}_{\overline{k}}^{\triangleright}$ to the various copies of **étale-like** data $\mathcal{O}_{\overline{k}}^{\triangleright}(\Pi_X)$, which are **coric** [cf. the discussion of §2.7, (iv)] with respect to the "**link**" constituted by the operation log.

(iv) The diagram of (iii) is, of course, **far from being commutative** [cf. the notation " \curvearrowright ?"], i.e., at least at the level of *images of elements* via the various composites of arrows in the diagram. On the other hand, if, instead of considering such images of elements via composites of arrows in the diagram, one considers **regions** [i.e., subsets] of [the union with $\{0\}$ of the *groupification* of] $\mathcal{O}_k^{\triangleright}$ ($\subseteq \mathcal{O}_{\overline{k}}^{\triangleright}$) or $\mathcal{O}_k^{\triangleright}(\Pi_X)$ ($\subseteq \mathcal{O}_{\overline{k}}^{\triangleright}(\Pi_X)$), then one verifies easily that the following *observation* holds:

Write

$$\mathcal{I} \stackrel{\text{def}}{=} (2p)^{-1} \cdot \log_{\overline{k}}(\mathcal{O}_{k}^{\times}) \subseteq k = \{0\} \cup (\mathcal{O}_{k}^{\triangleright})^{\text{gp}}$$

and $\mathcal{I}(\Pi_X) \subseteq \{0\} \cup \mathcal{O}_k^{\triangleright}(\Pi_X)^{\mathrm{gp}}$ for the corresponding subset of the union with $\{0\}$ of the groupification of $\mathcal{O}_k^{\triangleright}(\Pi_X)$. Then we have **inclusions of** "**regions**"

$$\mathcal{O}_k^{\triangleright} \subseteq \mathcal{I} \supseteq \log_{\overline{k}}(\mathcal{O}_k^{\times})$$

within \mathcal{I} , as well as corresponding inclusions for $\mathcal{I}(\Pi_X)$.

The compact "region" \mathcal{I} , which is referred to as the **log-shell**, plays an important role in inter-universal Teichmüller theory. Note that one has both **Frobenius-like**

[i.e., \mathcal{I}] and **étale-like** [i.e., $\mathcal{I}(\Pi_X)$] versions of the log-shell. Here, we observe that, from the point of view of the discussion of **arithmetic holomorphic structures** in §2.7, (vii), both of these versions are **holomorphic** in the sense that they depend, at least in an *a priori* sense, on " $\log_{\overline{k}}$ ", i.e., which is defined in terms of a *power series* that only makes sense if one is equipped with *both* " \boxplus " and " \boxtimes " [i.e., both the additive and multiplicative structures of the ring \overline{k}]. On the other hand, if one writes

"
$$\mathcal{O}^{\times \mu}$$
"

for the quotient of " \mathcal{O}^{\times} " by its torsion subgroup [i.e., by the roots of unity], then $\log_{\overline{k}}$ determines natural bijections of topological modules

$$\mathcal{O}_k^{\times \boldsymbol{\mu}} \otimes \mathbb{Q} \stackrel{\sim}{\to} \mathcal{I} \otimes \mathbb{Q}, \quad \mathcal{O}_k^{\times \boldsymbol{\mu}}(\Pi_X) \otimes \mathbb{Q} \stackrel{\sim}{\to} \mathcal{I}(\Pi_X) \otimes \mathbb{Q}$$

— i.e., within which the lattices $\mathcal{O}_k^{\times \mu} \otimes (2p)^{-1}$, $\mathcal{O}_k^{\times \mu}(\Pi_X) \otimes (2p)^{-1}$ correspond, respectively, to $\mathcal{I}, \mathcal{I}(\Pi_X)$. In particular, by applying these *bijections*,

we may think of the topological modules \mathcal{I} , $\mathcal{I}(\Pi_X)$ as objects constructed from the topological modules $\mathcal{O}_k^{\times \mu}$, $\mathcal{O}_k^{\times \mu}(G_k)$ [cf. the notation introduced at the beginning of the present §2.12; the notation of Example 2.12.1, (iv)], i.e., as objects constructed from mono-analytic structures [cf. the discussion of §2.7, (vii)].

That is to say, in addition to the **holomorphic Frobenius-like** and **holomorphic étale-like** versions of the *log-shell* discussed above, we also have **mono-analytic Frobenius-like** and **mono-analytic étale-like** versions of the **log-shell**. All four of these versions of the log-shell play an important role in inter-universal Teichmüller theory [cf. the discussion of §3.6, (iv), below; [IUTchIII], Definition 1.1, (i), (iv); [IUTchIII], Proposition 1.2, (v), (vi), (viii), (ix), (x); [IUTchIII], Remark 3.12.2, (iv), (v)]. Returning to the issue of the *non-commutativity* [i.e., " \sim ?"] of the *diagram* of (iii), we observe the following:

the inclusions of "regions" discussed above may be interpreted as asserting that the holomorphic étale-like log shell $\mathcal{I}(\Pi_X)$ serves as a **container** for [i.e., as a "region" that contains] the **images** — i.e., of $\mathcal{O}_k^{\triangleright}$, $\mathcal{O}_k^{\times} \subseteq \mathcal{O}_k^{\triangleright}$, or, in the case of multiple iterates of \log , even smaller subsets of \mathcal{O}_k^{\times} — via all **possible composites** of arrows of the diagram of (iii) [including the "..." on the left- and right-hand sides of the diagram!].

This property of the log-shell is referred to as **upper semi-commutativity** [cf. [IUTchIII], Remark 1.2.2, (i), (iii)]. Thus, this property of upper semi-commutativity constitutes a sort of **Kummer-detachment indeterminacy** [cf. the discussion of §2.7, (vi)] and may be regarded as an *answer* to the question of **computing** the **discrepancy** between the **two Kummer theories** in the domain and codomain of the **link** "log" [cf. the discussion at the beginning of §2.9]. Another important answer, in the context of inter-universal Teichmüller theory, to this computational question is given by the theory of **log-volumes** [i.e., where we use the term *log-volume* to refer to the *natural logarithm* of the *volume* $\in \mathbb{R}_{>0}$ of a region]:

There is a natural definition of the notion of the log-volume $\in \mathbb{R}$ of a region [i.e., compact open subset] of $k = \{0\} \cup (\mathcal{O}_k^{\triangleright})^{gp}$, which is normalized so

that the log-volume of \mathcal{O}_k is 0, while the log-volume of $p \cdot \mathcal{O}_k$ is $-\log(p)$. This log-volume is **compatible** [in the evident sense] with passage between the four versions of log-shells discussed above, as well as with log in the sense that it assumes the same value $\in \mathbb{R}$ on regions that are mapped bijectively to one another via $\log_{\overline{k}}$ [cf. [AbsTopIII], Proposition 5.7, (i); [IUTchIII], Proposition 1.2, (iii); [IUTchIII], Proposition 3.9, (i), (ii), (iv)].

These properties of **upper semi-commutativity** and **log-volume compatibility** will be sufficient for the purposes of inter-universal Teichmüller theory.

(v) Finally, we observe that since the operation log — which maps

$$\boxtimes \leadsto \boxplus$$

and relates unit groups [cf. $(\mathcal{O}_{\overline{k}}^{\times})^{\mathrm{pf}}$] to value groups [i.e., non-zero non-units of \overline{k}] — may be thought of as an operation that "juggles", or "rotates", the two underlying combinatorial dimensions [cf. the discussion of §2.11] of the ring \overline{k} [cf. [AbsTopIII], §13], one may think of this operation \log , relative to the analogy discussed in §2.2, §2.3, §2.4, §2.5, and §2.7 with the classical theory of §1.4 and §1.5, as corresponding to the discussion of the effect on "local masses" of the rotations that appeared in the discussion of Step 7 of §1.5.

§2.13. Mono-anabelian transport for monoids of rational functions: Let k be either an MLF or an NF; X a hyperbolic curve of strictly Belyi type [cf. [AbsTopII], Definition 3.5] over k; \overline{K}_X an algebraic closure of the function field K_X of X; $\overline{k} \subseteq \overline{K}_X$ the algebraic closure of k determined by \overline{K}_X . Write $\mu_{\overline{k}} \subseteq \overline{k}$ for the group of roots of unity of \overline{k} ; $\mu_{\overline{k}}^{\mathbb{Z}} \stackrel{\text{def}}{=} \text{Hom}(\mathbb{Q}/\mathbb{Z}, \mu_{\overline{k}})$; $G_X \stackrel{\text{def}}{=} \text{Gal}(\overline{K}_X/K_X)$; $G_k \stackrel{\text{def}}{=} \text{Gal}(\overline{k}/k)$; $G_X \twoheadrightarrow \Pi_X$ for the quotient of G_X determined by the maximal subextension of \overline{K}_X that is unramified over X [so Π_X may be thought of, for a suitable choice of basepoint, as the étale fundamental group of X]. Thus, when k is an MLF, X and Π_X are as in Example 2.12.3, (i). Here, for simplicity, we assume further that X is of genus ≥ 1 , and write $\Delta_X \stackrel{\text{def}}{=} \text{Ker}(\Pi_X \twoheadrightarrow G_k)$; X^{cp} for the natural [smooth, proper] compactification of X; $\Delta_X \twoheadrightarrow \Delta_X^{\text{cp}}$ for the quotient of Δ_X by the cuspidal inertia groups of Δ_X [so Δ_X^{cp} may be naturally identified with the étale fundamental group, for a suitable basepoint, of $X^{\text{cp}} \times_k \overline{k}$];

$$M_X \stackrel{\text{def}}{=} \operatorname{Hom}_{\widehat{\mathbb{Z}}}(H^2(\Delta_X, \widehat{\mathbb{Z}}), \widehat{\mathbb{Z}})$$

[so M_X ($\cong \widehat{\mathbb{Z}}$) is a *cyclotome* naturally associated to Δ_X — cf. [AbsTopIII], Proposition 1.4, (ii)]. Here, we recall that the quotient $\Delta_X \to \Delta_X^{\text{cp}}$, hence also the cyclotome M_X , may be constructed by means of a *purely group-theoretic algorithm* from the *abstract topological group* Π_X [cf. [AbsTopI], Lemma 4.5, (v); [IUTchI], Remark 1.2.2, (ii)]. Now *observe* that

the **Frobenius-like** data that appears in the various examples [i.e., Examples 2.12.1, 2.12.2, 2.12.3] of **mono-anabelian transport** discussed in §2.12 only involve the **two underlying combinatorial dimensions** of [various portions of] the ind-topological monoid " $\mathcal{O}_{\overline{k}}^{\triangleright}$ " of these examples.

That is to say, although, for instance, the **étale-like** data [i.e., " Π_X "] that appears in Example 2.12.3 involves the relative **geometric dimension** of X over k [i.e., in the case where k is an MLF], the Frobenius-like data [i.e., " $\mathcal{O}_k^{\triangleright}$ "] that appears in these examples does **not** involve this geometric dimension of X over k. On the other hand, in inter-universal Teichmüller theory, it will be of crucial importance [cf. the discussion of §3.4, §3.6, below; [IUTchIII], Remark 2.3.3] to consider such Frobenius-like data that involves the geometric dimension of X over K i.e., in more concrete terms, to consider **non-constant rational functions** on X — together with various **evaluation** operations that arise by evaluating such functions on various "**special points**" of X [or coverings of X]. In fact, the fundamental importance of such evaluation operations may also be seen in the discussion of §2.14, (i), (ii), (iii), below. In the remainder of the present §2.13, we discuss what is perhaps the most fundamental example of **cyclotomic rigidity** and **mono-anabelian transport** for such geometric functions.

Example 2.13.1: Monoids of rational functions.

(i) In the following, we assume for simplicity that the field k is an **NF**. Recall that consideration of the *first Chern class* of a line bundle of degree 1 on X yields a natural isomorphism

$$\lambda: \mu_{\overline{k}}^{\widehat{\mathbb{Z}}} \stackrel{\sim}{ o} M_X$$

— cf., e.g., Example 2.6.1, (iii); [the evident NF version of] [Cusp], Proposition 1.2, (ii). Next, observe that by considering the action of G_X on the various N-th roots, for N a positive integer, of elements of K_X^{\times} ($\stackrel{\text{def}}{=}$ $K_X \setminus \{0\}$), we obtain a natural **Kummer map**

$$\kappa_X: K_X^{\times} \hookrightarrow H^1(G_X, \boldsymbol{\mu}_{\overline{k}}^{\widehat{\mathbb{Z}}})$$

— which may be *composed* with the natural isomorphism λ to obtain a natural embedding

$$\kappa_X^{\text{Gal}}: K_X^{\times} \hookrightarrow H^1(G_X, M_X)$$

— where we recall from the theory of [AbsTopIII], §1 [cf. [AbsTopIII], Theorem 1.9] that the Galois group G_X [regarded up to inner automorphisms that arise from elements of $\operatorname{Ker}(G_X \to \Pi_X)$], together with the cohomology module in the codomain of $\kappa_X^{\operatorname{Gal}}$, the image of $\kappa_X^{\operatorname{Gal}}$ in this cohomology module, and the field structure on the union $K_X(\Pi_X)^{\operatorname{Kum}}$ of this image with $\{0\}$, may be **constructed group-theoretically** from the abstract topological group Π_X . Write $G_X(\Pi_X)$ for " G_X regarded as an object constructed in this way from Π_X ";

$$\overline{K}_X(\Pi_X)^{\text{Kum}}
ightharpoonup G_X(\Pi_X)$$

for the inductive system/limit [which, by functoriality, is equipped with a natural action by $G_X(\Pi_X)$] of the result of applying this group-theoretic construction $\Pi_X \mapsto K_X(\Pi)^{\text{Kum}}$ to the various open subgroups of $G_X(\Pi_X)$.

(ii) Now let us regard the pair " $G_X \curvearrowright \overline{K}_X^{\times}$ " as an abstract ind-monoid " \overline{K}_X^{\times} " [i.e., inductive system of monoids] equipped with a continuous action by an abstract topological group " G_X " that arises, for some abstract quotient topological group " $G_X \twoheadrightarrow \Pi_X$ ", as the topological group " $G_X(\Pi_X)$ " of (i) [hence is only well-defined up to inner automorphisms that arise from elements of $\operatorname{Ker}(G_X \twoheadrightarrow \Pi_X)$]. Thus, if

we think of $\mu_{\overline{k}} \subseteq \overline{K}_X^{\times}$ as the *subgroup of torsion elements* of the monoid \overline{K}_X^{\times} , then, by considering the action of G_X on the various N-th roots, for N a positive integer, of elements of K_X^{\times} , we obtain the natural **Kummer map**

$$\kappa_X: K_X^{\times} \hookrightarrow H^1(G_X, \boldsymbol{\mu}_{\overline{k}}^{\widehat{\mathbb{Z}}})$$

discussed in (i). Moreover,

the $\{\pm 1\}$ -orbit of the cyclotomic rigidity isomorphism $\lambda: \mu_{\overline{k}}^{\widehat{\mathbb{Z}}} \stackrel{\sim}{\to} M_X$ of (i) may be constructed functorially from the data " $G_X \curvearrowright \overline{K}_X^{\times}$ "

by applying the "alternative approach" discussed in Example 2.12.1, (iv), as follows [cf. [IUTchI], Example 5.1, (v); [IUTchI], Definition 5.2, (vi)]. Indeed, it follows formally from the elementary fact

$$\mathbb{Q}_{>0} \bigcap \widehat{\mathbb{Z}}^{\times} = \{1\}$$

— for instance, by considering the various quotients $K_X^{\times} \to \mathbb{Z}$ determined by the discrete valuations of K_X that arise from the closed points of X^{cp} , i.e., the quotients which, at the level of Kummer classes, are induced by restriction to the various cuspidal inertia groups [cf. the first display of [AbsTopIII], Proposition 1.6, (iii)] — that

the only isomorphisms $\mu_{\overline{k}}^{\widehat{\mathbb{Z}}} \stackrel{\sim}{\to} M_X$ that map the image of κ_X into $K_X^{\times}(\Pi_X)^{\operatorname{Kum}} \stackrel{\text{def}}{=} K_X(\Pi_X)^{\operatorname{Kum}} \setminus \{0\}$ are the isomorphisms that belong to the $\{\pm 1\}$ -orbit of λ .

As discussed in Example 2.12.1, (iv) [cf. also the discussion of [IUTchIII], Remark 2.3.3, (vii)], this approach to cyclotomic rigidity has the **disadvantage** of being **incompatible** with the **profinite topology** of G_X [or Π_X].

(iii) We continue to use the notational conventions of (ii). Then observe that the functorial construction of the $\{\pm 1\}$ -orbit of the cyclotomic rigidity isomorphism λ given in (ii) may be interpreted in the fashion of Example 2.12.2, (i). That is to say, observe that this functorial construction implies that if α is an arbitrary automorphism of the data " $G_X \curvearrowright \overline{K}_X^{\times}$ ", then either α or $-\alpha$ [i.e., the composite of α with the automorphism of the data " $G_X \curvearrowright \overline{K}_X^{\times}$ " that raises elements of \overline{K}_X^{\times} to the power -1 and acts as the identity on G_X] — but not both! — is compatible with λ , hence also with κ_X^{Gal} . In particular, by applying this observation to the various open subgroups of G_X , one concludes that one has a natural bijection

$$\operatorname{Aut}(G_X \curvearrowright \overline{K}_X^{\times}) \stackrel{\sim}{\to} \{\pm 1\} \times \operatorname{Aut}(\Pi_X)$$

— where the first "Aut(-)" denotes automorphisms of the data " $G_X \curvearrowright \overline{K}_X^{\times}$ " as described at the beginning of (ii); the second "Aut(-)" denotes automorphisms of the data " Π_X " consisting of an abstract topological group [cf. the discussion of [IUTchI], Example 5.1, (v); [IUTchI], Definition 5.2, (vi)]. Just as in the case of Example 2.12.2, (i), this situation may also be understood in terms of the general

framework of **mono-anabelian transport** discussed in §2.7, (v) [cf. also Example 2.6.1, (iii), (iv)], by considering the *commutative diagram*

$$\overline{K}_{X}^{\times}(\Pi_{X})^{\operatorname{Kum}} \stackrel{\sim}{\longrightarrow} \overline{K}_{X}^{\times}(\Pi_{X})^{\operatorname{Kum}}$$

$$\uparrow^{\operatorname{Kum}} \qquad \curvearrowright ? \qquad \uparrow^{\operatorname{Kum}}$$

$$\overline{K}_{X}^{\times} \qquad \stackrel{\sim}{\longrightarrow} \qquad \overline{K}_{X}^{\times}$$

- where $\overline{K}_X^{\times}(\Pi_X)^{\operatorname{Kum}} \stackrel{\text{def}}{=} \overline{K}_X(\Pi_X)^{\operatorname{Kum}} \setminus \{0\}$; the horizontal arrows are induced by some given automorphism of the data " $G_X \curvearrowright \overline{K}_X^{\times}$ "; the vertical arrows, which relate the **Frobenius-like** data \overline{K}_X^{\times} to the **étale-like** data $\overline{K}_X^{\times}(\Pi_X)^{\operatorname{Kum}}$, are the "**Kummer isomorphisms**" determined by the various " $\kappa_X^{\operatorname{Gal}}$ " associated to open subgroups of G_X ; the diagram commutes [cf. " \curvearrowright ?"] up to the action of a suitable element $\in \{\pm 1\}$.
- (iv) Finally, we pause to remark that one **fundamental reason** for the use of **Kummer theory** in inter-universal Teichmüller theory in the context of **non-constant rational functions** [i.e., as in the discussion of the present Example 2.13.1] lies in

the **functoriality** of Kummer theory with respect to the operation of **evaluation** of such functions at "special points" of X.

That is to say, [cf. the discussion of Example 2.6.1, (ii), (iii); §2.7, (vii)] although there exist many different versions — e.g., versions for "higher-dimensional fields" — of class field theory, these versions of class field theory do not satisfy such functionality properties with respect to the operation of evaluation of functions at points [cf. the discussion of §2.14, §3.6, §4.2, below; [IUTchIV], Remark 2.3.3, (vi), (vii)].

- §2.14. Finite discrete approximations of harmonic analysis: Finally, we conclude the present §2 by pausing to examine in a bit more detail the *transition* that was, in effect, made earlier in the present §2 in passing from **derivatives** [in the literal sense, as in the discussion of §2.5] to **Galois groups/étale fundamental groups** [i.e., as in the discussion of and subsequent to §2.6]. This transition is closely related to many of the ideas of the [scheme-theoretic] **Hodge-Arakelov theory** of [HASurI], [HASurII].
- Example 2.14.1: Finite discrete approximation of differential calculus on the real line. We begin by recalling that the differential calculus of [say, infinitely differentiable] functions on the real line admits a finite discrete approximation, namely, by substituting

$$\frac{df(x)}{dx} = \lim_{\delta \to 0} \frac{f(x+\delta) - f(x)}{\delta} \longrightarrow f(X+1) - f(X)$$

difference operators for derivatives [in the classical sense]. If d is a positive integer, then one verifies easily, by considering such difference operators in the case of polynomial functions of degree < d with coefficients $\in \mathbb{Q}$, that **evaluation** at the

elements $0, 1, \ldots, d-1 \in \mathbb{Z} \subseteq \mathbb{Q}$ yields a natural isomorphism of \mathbb{Q} -vector spaces of dimension d

$$\mathbb{Q}[X]^{< d} \ \left(\stackrel{\text{def}}{=} \ \bigoplus_{j=0}^{d-1} \ \mathbb{Q} \cdot X^j \right) \quad \stackrel{\sim}{\to} \quad \bigoplus_{0}^{d-1} \ \mathbb{Q}$$

— cf., e.g., the discussion of the well-known classical theory of *Hilbert polynomials* in [Harts], Chapter I, §7, for more details. In fact, it is not difficult to compute explicitly the "denominators" necessary to make this evaluation isomorphism into an isomorphism of finite free Z-modules. This sort of "discrete function theory" [cf. also Example 2.14.2 below] may be regarded as the **fundamental prototype** for the various constructions of Hodge-Arakelov theory.

Example 2.14.2: Finite discrete approximation of Fourier analysis on the unit circle. In the spirit of the discussion of Example 2.14.1, we recall that classical function theory — i.e., in effect, Fourier analysis — on the unit circle \mathbb{S}^1 admits a well-known finite discrete approximation: If d is a(n) [say, for simplicity] odd positive integer, so $d^* \stackrel{\text{def}}{=} \frac{1}{2}(d-1) \in \mathbb{Z}$, then one verifies easily that evaluation of polynomial functions of degree $\in \{-d^*, -d^* + 1, \dots, -1, 0, 1, d^* - 1, d^*\}$ with coefficients $\in \mathbb{Z}$ on the multiplicative group scheme $\mathbb{G}_{\mathbf{m}} \stackrel{\text{def}}{=} \operatorname{Spec}(\mathbb{Z}[U, U^{-1}])$ at [say, scheme-theoretic] points of the subscheme $\mu_d \subseteq \mathbb{G}_{\mathbf{m}}$ of d-torsion points of $\mathbb{G}_{\mathbf{m}}$ yields a natural isomorphism of finite free \mathbb{Z} -modules of rank d

$$\bigoplus_{j=-d^*}^{d^*} \mathbb{Z} \cdot U^j \quad \stackrel{\sim}{\to} \quad \mathcal{O}_{\boldsymbol{\mu}_d}$$

— where, by abuse of notation, we write \mathcal{O}_{μ_d} for the ring of global sections of the structure sheaf of the affine scheme μ_d . If one base-changes via the natural inclusion $\mathbb{Z} \hookrightarrow \mathbb{C}$ into the field of complex numbers \mathbb{C} , then, when d is sufficiently "large", one may think of the totality of these d-torsion points

$$\exp(2\pi i \cdot \frac{1}{d}\mathbb{Z}) = \left\{ \exp(2\pi i \cdot \frac{0}{d}), \exp(2\pi i \cdot \frac{1}{d}), \dots, \exp(2\pi i \cdot \frac{(d-1)}{d}) \right\} \subseteq \mathbb{S}^1$$

as a sort of **finite discrete approximation** of \mathbb{S}^1 and hence, in particular, of adjacent pairs of d-torsion points as "tangent vectors" on \mathbb{S}^1 . That is to say, since [inverse systems of] such torsion points give rise to the étale fundamental group of $\mathbb{G}_m \times_{\mathbb{Z}} \mathbb{C}$, it is precisely this "picture" of torsion points of \mathbb{S}^1 that motivates the idea that

Galois groups/étale fundamental groups should be regarded as a sort of arithmetic analogue of the classical geometric notion of a tangent bundle

- the discussion of §2.6. Moreover, if one regards \mathbb{G}_{m} as the codomain of a nonzero function [on some unspecified "space"], then this very classical "pictorial representation of a cyclotome" [i.e., of torsion points of \mathbb{S}^1] also explains, from a "pictorial point of view", the importance of cyclotomes and Kummer classes in the discussion of §2.6, §2.7. That is to say,
 - a Kummer class of a function, which, so to speak, records the "arithmetic infinitesimal motion" in \mathbb{G}_{m} induced, via the function, by an "arithmetic infinitesimal motion" in the space on which the function is defined

may be thought of as a sort of "arithmetic logarithmic derivative" of the function

— a point of view that is consistent with the usual point of view that the Kummer exact sequence in étale cohomology [i.e., which induces a connecting homomorphism in cohomology that computes the Kummer class of a function] should be thought of as a sort of arithmetic analogue of the *exponential exact sequence* $1 \to 2\pi i \cdot \mathbb{Z} \to \mathbb{C} \to \mathbb{C}^{\times} \to 1$ that appears in the theory of sheaf cohomology of sheaves of holomorphic functions on a complex space.

Example 2.14.3: Finite discrete approximation of harmonic analysis on complex tori. Examples 2.14.1 and 2.14.2 admit a natural generalization to the case of elliptic curves. Indeed, let E be an elliptic curve over a field F of characteristic zero, $E^{\dagger} \to E$ the universal extension of E, $\eta \in E(F)$ a [nontrivial] torsion point of order 2, $l \neq 2$ a prime number. Write $E[l] \subseteq E$ for the subscheme of l-torsion points, $\mathcal{L} \stackrel{\mathrm{def}}{=} \mathcal{O}_E(\eta)$ [where we regard η as an effective divisor on E]. Here, we recall that $E^{\dagger} \to E$ is an \mathbb{A}^1 -torsor [so E[l] may also be regarded as the subscheme $\subseteq E^{\dagger}$ of l-torsion points of E^{\dagger}]. In particular, it makes sense to speak of the sections $\Gamma(E^{\dagger}, \mathcal{L}|_{E^{\dagger}})^{< l} \subseteq \Gamma(E^{\dagger}, \mathcal{L}|_{E^{\dagger}})$ of \mathcal{L} over E^{\dagger} whose relative degree, with respect to the morphism $E^{\dagger} \to E$, is < l. Then the simplest version of the fundamental theorem of Hodge-Arakelov theory states that evaluation at the subscheme of l-torsion points $E[l] \subseteq E^{\dagger}$ yields a natural isomorphism of F-vector spaces of dimension l^2

$$\Gamma(E^{\dagger}, \mathcal{L}|_{E^{\dagger}})^{< l} \stackrel{\sim}{\to} \mathcal{L}|_{E[l]}$$

[cf. [HASurI], Theorem A^{simple}]. Moreover:

- When F is an **NF**, this isomorphism is compatible, up to mild discrepancies, with **natural integral structures** on the LHS and RHS of the isomorphism at the nonarchimedean valuations of F and with **natural Hermitian metrics** on the LHS and RHS of the isomorphism at the archimedean valuations of F.
- When F is a complete discrete valuation field, and E is a **Tate curve** over F, with special fiber isomorphic to \mathbb{G}_{m} , **Example 2.14.2** may be thought of as corresponding to the portion of the natural isomorphism of the above display that arises from the "special fiber of E", while **Example 2.14.1** may be thought of as corresponding to the portion of the natural isomorphism of the above display that arises from the "special fiber of the relative dimension of the morphism $E^{\dagger} \to E$ ".
- When E is a **Tate curve**, the isomorphism, over F, of the above display may be interpreted as a result concerning the *invertibility of the matrix* determined by the values at the l-torsion points of certain **theta functions** associated to the Tate curve and their **derivatives of order** < l [cf., §3.6 below; [Fsk], §2.5; [EtTh], Proposition 1.4, for a review of the series representation of such theta functions].
- When F is an arbitrary field, the isomorphism of the above display may be thought of as a sort of **discrete polynomial version** of the **Gaussian integral** $\int_{-\infty}^{\infty} e^{-x^2} dx = \sqrt{\pi}$, i.e., in the spirit of the discussion of Examples 2.14.1 and 2.14.2, above.

- When F is an \mathbf{NF} , the isomorphism of the above display may be thought of as a sort of **discrete globalized version** of the **harmonic analysis** involving " ∂ , $\overline{\partial}$, Green's functions, etc." that appears at archimedean valuations in classical **Arakelov theory**. This is the reason for the appearance of the word "Arakelov" in the term "Hodge-Arakelov theory". From this point of view, the computation of the discrepancy between natural integral structures/metrics on the LHS and RHS of the isomorphism of the above display may be thought of as a sort of computation of **analytic torsion** a point of view that in some sense foreshadows the interpretation [cf. the discussion of §3.9, (iii), below] of inter-universal Teichmüller theory as the **computation** of a sort of **global arithmetic/Galois-theoretic** form of **analytic torsion**.
- Relative to the point of view of "filtered crystals" [e.g., vector bundles equipped with a connection and filtration cf. the data $(\mathcal{E}, \nabla_{\mathcal{E}}, \omega_E \subseteq \mathcal{E})$ of §2.9], the isomorphism of the above display may be thought of as a sort of **discrete Galois-theoretic version** of the "**crystalline theta object**" [cf. [HASurII], §2], i.e., the "**nonlinear filtered crystal**" constituted by the universal extension E^{\dagger} equipped with the ample line bundle $\mathcal{L}|_{E^{\dagger}}$, the natural structure of crystal on $(E^{\dagger}, \mathcal{L}|_{E^{\dagger}})$, and the "filtration" constituted by the morphism $E^{\dagger} \to E$.

We refer to [HASurI], [HASurII], for more details concerning the ideas just discussed.

Section 3: Multiradiality: an abstract analogue of parallel transport

§3.1. The notion of multiradiality: So far, in §2, we have discussed various generalities concerning arithmetic changes of coordinates [cf. §2.10; the analogy discussed in §2.2, §2.5, and §2.7 with the classical theory of §1.4 and §1.5], which are applied in effect to the **two underlying combinatorial dimensions** of a ring such as an MLF or an NF [cf. §2.7, (vii); §2.11; §2.12], and the approach to computing the effect of such arithmetic changes of coordinates — i.e., in the form of **Kummer-detachment indeterminacies** or étale-transport indeterminacies [cf. §2.7, (vi); §2.9] — by means of the technique of **mono-anabelian transport**

- [cf. §2.7, (v)]. By contrast, in the present §3, we turn to the issue of considering the **particular** arithmetic changes of coordinates that are of interest in the context of inter-universal Teichmüller theory [cf. the discussion of §2.1, §2.3, §2.4]. Many aspects of these particular arithmetic changes of coordinates are highly reminiscent of the change of coordinates discussed in §1.6 from **planar cartesian** to **polar** coordinates. In some sense, the central notion that underlies the abstract combinatorial analogue, i.e., that is developed in inter-universal Teichmüller theory, of this change of coordinates from planar cartesian to polar coordinates is the notion of **multiradiality**.
- (i) Types of mathematical objects: In the following discussion, we shall often speak of "types of mathematical objects", i.e., such as groups, rings, topological spaces equipped with some additional structure, schemes, etc. This notion of a "type of mathematical object" is formalized in [IUTchIV], §3, by introducing the notion of a "species". On the other hand, the details of this formalization are not so important for the following discussion of the notion of multiradiality. A "type of mathematical object" determines an associated category consisting of mathematical objects of this type — i.e., in a given universe, or model of set theory — and morphisms between such mathematical objects. On the other hand, in general, the structure of this associated category [i.e., as an abstract category!] contains considerably less information than the information that determines the "type of mathematical object" that one started with. For instance, if p is a prime number, then the "type of mathematical object" given by rings isomorphic to $\mathbb{Z}/p\mathbb{Z}$ [and ring homomorphisms] yields a category whose equivalence class as an abstract category is manifestly independent of the prime number p.
- (ii) Radial environments: A radial environment consists of a triple. The first member of this triple is a specific "type of mathematical object" that is referred to as radial data. The second member of this triple is a specific "type of mathematical object" that is referred to as coric data. The third member of this triple is a functorial algorithm that inputs radial data and outputs coric data; this algorithm is referred to as radial, while the resulting functor from the category of radial data to the category of coric data is referred to as the radial functor of the radial environment. We would like to think of the coric data as a sort of "underlying structure" of the "finer structure" constituted by the radial data and of the radial algorithm as an algorithm that forgets this "finer structure", i.e., an algorithm that assigns to a collection of radial data the collection of underlying coric data of this given collection of radial data. We refer to [IUTchII], Example 1.7, (i), (ii), for more details.
- (iii) <u>Multiradiality and uniradiality</u>: A radial environment is called <u>multiradial</u> if its associated radial functor is *full*. A radial environment is called <u>uniradial</u> if its associated radial functor is *not full*. One important consequence of the condition of *multiradiality* is the following **switching property**:

Consider the category of *objects* consisting of an *ordered pair* of collections of radial data, together with an *isomorphism* between the associated collections of *underlying coric data* [and *morphisms* defined in the evident way]. Observe that this category admits a **switching functor** [from the category to itself] that assigns to an object of the category the object obtained by *switching* the two collections of radial data of the given object

and replaces the isomorphism between associated collections of underlying coric data by the *inverse* to this isomorphism. Then **multiradiality** implies that the switching functor preserves the isomorphism classes of objects.

Indeed, one verifies immediately that multiradiality is in fact equivalent to the property that any object of the category discussed in the above display is, in fact, isomorphic to a "diagonal object", i.e., an object given by considering an ordered pair of copies of a given collection of radial data, together with the identity isomorphism between the associated collections of underlying coric data — cf. the illustration of Fig. 3.1 below. We refer to [IUTchII], Example 1.7, (ii), (iii), for more details.

(iv) Analogy with the Grothendieck definition of a connection: Thus, in summary,

multiradiality concerns the issue of comparison between two collections of radial data that share a common collection of underlying coric data.

We shall often think of this sort of comparison as a comparison between **two "holo**morphic structures" that share a common "underlying real analytic structure" [cf. the examples discussed in §3.2 below]. Note that multiradiality may be thought of as a sort of abstract analogue of the notion of "parallel transport" or, alternatively, the Grothendieck definition of a connection [cf. the discussion of [IUTchII], Remark 1.7.1]. That is to say, given a scheme X over a scheme S, the Grothendieck definition of a connection on an object \mathcal{E} over X consists of an isomorphism between the fibers of \mathcal{E} at two distinct — but infinitesimally close! points of X that map to the same point of S. Thus, one may think of the fullness condition of multiradiality as the condition that there exist a sort of parallel transport isomorphism between two collections of radial data [i.e., corresponding to two "fibers" that lifts a given isomorphism between collections of underlying coric data i.e., corresponding to a path between the points over which the two fibers lie. The **indeterminacy** in the *choice* of such a lifting may then be thought of, relative to this analogy with parallel transport, as a sort of "monodromy" associated to the multiradial environment.

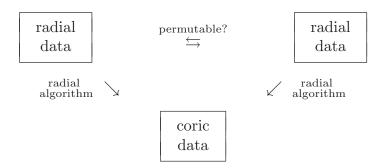

Fig. 3.1: Multiradiality vs. uniradiality

§3.2. Fundamental examples of multiradiality: The following examples may be thought of as fundamental prototypes of the phenomenon of multiradiality.

<u>Example 3.2.1</u>: Complex holomorphic structures on two-dimensional real vector spaces.

(i) Consider the radial environment in which the radial data is given by one-dimensional \mathbb{C} -vector spaces [and isomorphisms between such data], the **coric** data is given by two-dimensional \mathbb{R} -vector spaces [and isomorphisms between such data], and the radial algorithm assigns to a one-dimensional \mathbb{C} -vector space the associated underlying \mathbb{R} -vector space. Then one verifies immediately that this radial environment, shown in Fig. 3.2 below, is uniradial [cf. [Pano], Figs. 2.2, 2.3].

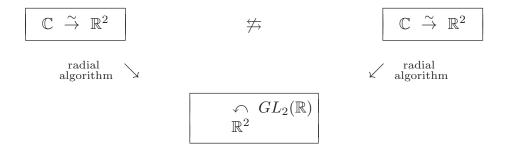

Fig. 3.2: The uniradiality of complex holomorphic structures

(ii) If V is a two-dimensional real vector space, then write $\operatorname{End}(V)$ for the \mathbb{R} -algebra of \mathbb{R} -linear endomorphisms of V and GL(V) for the group of invertible elements of $\operatorname{End}(V)$. Observe that if V is a two-dimensional real vector space, then a $\operatorname{complex}$ — i.e., "holomorphic" — structure on V may be thought of as a homomorphism of \mathbb{R} -algebras $\mathbb{C} \to \operatorname{End}(V)$. In particular, it makes sense to speak of a GL -orbit of complex structures on V, i.e., the set of $\operatorname{GL}(V)$ -conjugates of some such homomorphism. Now consider the radial environment in which a collection of radial data consists of a two-dimensional \mathbb{R} -vector space equipped with a GL -orbit of complex structures [and the morphisms between such data are taken to be the isomorphisms between such data], the coric data is the same as the coric data of (i), and the radial algorithm assigns to a two-dimensional \mathbb{R} -vector space equipped with a GL -orbit of complex structures the associated underlying \mathbb{R} -vector space. Then one verifies immediately that this radial environment, shown in Fig. 3.3 below, is ["tautologically"!] multiradial [cf. [Pano], Figs. 2.2, 2.3].

Fig. 3.3: The multiradiality of $GL_2(\mathbb{R})$ -orbits of complex holomorphic structures

(iii) The examples of radial environments discussed in (i), (ii) are particularly of interest in the context of inter-universal Teichmüller theory in light of the relationship between *complex holomorphic structures* as discussed in (i), (ii) and the

geometry of the upper half-plane. That is to say, if, in the notation of (ii), we write $GL(V) = GL^+(V) \coprod GL^-(V)$ for the decomposition of GL(V) determined by considering the sign of the determinant of an \mathbb{R} -linear automorphism of V, then the space of **moduli of complex holomorphic structures** on V [i.e., the set of GL(V)-conjugates of a particular homomorphism of \mathbb{R} -algebras $\mathbb{C} \hookrightarrow \operatorname{End}(V)$] may be identified

$$GL(V)/\mathbb{C}^{\times} \stackrel{\sim}{\to} GL^+(V)/\mathbb{C}^{\times} \coprod GL^-(V)/\mathbb{C}^{\times} \stackrel{\sim}{\to} \mathfrak{H}^+ \coprod \mathfrak{H}^-$$

in a natural way with the disjoint union of the upper [i.e., \mathfrak{H}^+] and lower [i.e., \mathfrak{H}^-] half-planes. This observation is reminiscent of the deep connections between inter-universal Teichmüller theory and the **hyperbolic geometry** of the **upper half-plane**, as discussed in [BogIUT] [cf. also the discussion of §2.4, as well as of §4.1, (i), below, of the present paper]. This circle of ideas is also of interest, in the context of inter-universal Teichmüller theory, in the sense that it is reminiscent of the natural bijection

$$\begin{array}{ccc}
\mathbb{C}^{\times} \backslash GL^{+}(V) / \mathbb{C}^{\times} & \stackrel{\sim}{\to} & [0, 1) \\
\binom{t \ 0}{0 \ 1} & \mapsto & \frac{t-1}{t+1}
\end{array}$$

[where $\mathbb{R} \ni t \geq 1$] between the space of double cosets on the left and the semiclosed interval [0,1) on the right, i.e., a bijection that is usually interpreted in classical complex Teichmüller theory as the map that assigns to a **deformation** of complex structure the dilation \in [0,1) associated to this deformation [cf. [QuCnf], Proposition A.1, (ii)].

<u>Example 3.2.2</u>: Arithmetic fundamental groups of hyperbolic curves of strictly Belyi type over mixed-characteristic local fields.

(i) Let $X \to \operatorname{Spec}(k)$ and $\Pi_X \twoheadrightarrow G_k$ be as in Example 2.12.3, (i). Consider the radial environment in which the radial data is given by topological groups Π that "just happen to be" abstractly isomorphic as topological groups to Π_X [and isomorphisms between topological groups], the coric data is given by topological groups G that "just happen to be" abstractly isomorphic as topological groups to G_k [and isomorphisms between topological groups], and the radial algorithm assigns to a topological group Π the quotient group $\Pi \twoheadrightarrow G$ that corresponds to the [grouptheoretically constructible! — cf. the discussion of Example 2.12.3, (i)] quotient $\Pi_X \twoheadrightarrow G_k$. Then one verifies immediately [cf. the two displays of Example 2.12.3, (i)!] that this radial environment, shown in Fig. 3.4 below, is uniradial.

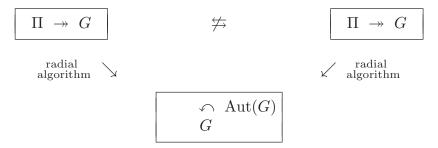

Fig. 3.4: The uniradiality of local arithmetic holomorphic structures

(ii) In the remainder of the present (ii), we apply the notation "Aut(-)" to denote the group of automorphisms of the topological group in parentheses. Consider the *radial environment* in which the **radial data** is given by triples

$$(\Pi, G, \alpha)$$

— where Π is a topological group as in the radial data of (i), G is a topological group as in the coric data of (i), and α is an $\operatorname{Aut}(G)$ -orbit of isomorphisms between G and the quotient of Π that corresponds to the [group-theoretically constructible!] quotient $\Pi_X \to G_k$ — [and isomorphisms between such triples], the **coric data** is the same as the coric data of (i), and the **radial algorithm** assigns to a triple (Π, G, α) the topological group G. Then one verifies immediately that this radial environment, shown in Fig. 3.5 below, is ["tautologically"!] multiradial [cf. [IUTchII], Example 1.8, (i)].

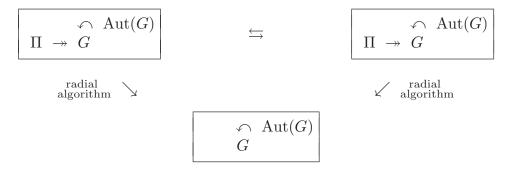

Fig. 3.5: The multiradiality of Aut(G)-orbits of local arithmetic holomorphic structures

- §3.3. The log-theta-lattice: $\Theta^{\pm \text{ell}}$ NF-Hodge theaters, log-links, Θ -links: The fundamental stage on which the constructions of inter-universal Teichmüller theory are performed is referred to as the log-theta-lattice.
- (i) <u>Initial Θ -data</u>: The *log-theta-lattice* is completely determined, up to isomorphism, once one fixes a collection of **initial** Θ -data. Roughly speaking, this data consists of
 - · an elliptic curve E_F over a number field F,
 - · an algebraic closure \overline{F} of F,
 - · a prime number $l \geq 5$,
 - · a collection of valuations $\underline{\mathbb{V}}$ of a certain subfield $K \subseteq \overline{F}$, and
 - · a collection of valuations $\overline{\mathbb{V}}_{\mathrm{mod}}^{\mathrm{bad}}$ of a certain subfield $F_{\mathrm{mod}} \subseteq \overline{F}$

that satisfy certain technical conditions — cf. [IUTchI], Definition 3.1, for more details. Here, we write $F_{\text{mod}} \subseteq F$ for the **field of moduli** of E_F , i.e., the field extension of \mathbb{Q} obtained by adjoining the **j-invariant** of E_F ; $K \subseteq \overline{F}$ for the extension field of F generated by the fields of definition of the **l-torsion points** of E_F ; $X_F \subseteq E_F$ for the **once-punctured elliptic curve** obtained by removing the origin from E_F ; and $X_F \to C_F$ for the hyperbolic orbicurve obtained by forming the stack-theoretic quotient of X_F by the natural action of $\{\pm 1\}$. Also, in the following, we shall write $\mathbb{V}(-)$ for the set of all [nonarchimedean and archimedean] valuations of an NF "(-)" and append a subscripted element $\in \mathbb{V}(-)$ to the NF to denote the completion of the NF at the element $\in \mathbb{V}(-)$. We assume further that the following conditions are satisfied [cf. [IUTchI], Definition 3.1, for more details]:

- · F is **Galois** over F_{mod} of degree **prime to** l and contains the fields of definition of the **2·3-torsion points** of E_F ;
- · the image of the natural inclusion $Gal(K/F) \hookrightarrow GL_2(\mathbb{F}_l)$ [well-defined

up to composition with an inner automorphism] contains $SL_2(\mathbb{F}_l)$;

- · E_F has **stable reduction** at all of the nonarchimedean valuations of F;
- · $C_K \stackrel{\text{def}}{=} C_F \times_F K$ is a K-core, i.e., does not admit a finite étale covering that is isomorphic to a finite étale covering of a **Shimura curve** [cf. [CanLift], Remarks 2.1.1, 2.1.2]; this condition implies that there exists a unique model $C_{F_{\text{mod}}}$ of C_F over F_{mod} [cf. the discussion of [IUTchI], Remark 3.1.7, (i)];
- $\underline{\mathbb{V}} \subseteq \mathbb{V}(K)$ is a subset such that the natural inclusion $F_{\text{mod}} \subseteq F \subseteq K$ induces a **bijection** $\underline{\mathbb{V}} \stackrel{\sim}{\to} \mathbb{V}_{\text{mod}}$ between $\underline{\mathbb{V}}$ and the set $\mathbb{V}_{\text{mod}} \stackrel{\text{def}}{=} \mathbb{V}(F_{\text{mod}})$; $\mathbb{V}_{\text{mod}}^{\text{bad}} \subseteq \mathbb{V}_{\text{mod}}$ is a **nonempty set** of nonarchimedean valuations of *odd* residue characteristic over which E_F has **bad** [i.e., **multiplicative**] reduction, that is to say, roughly speaking, the *subset* of the set of valuations where E_F has bad multiplicative reduction that will be "of interest" to us in the context of the constructions of inter-universal Teichmüller theory.

The above conditions in fact imply that K is Galois over F_{mod} [cf. [IUTchI], Remark 3.1.5]. We shall write

$$\underline{\mathbb{V}}^{\mathrm{bad}} \stackrel{\mathrm{def}}{=} \mathbb{V}^{\mathrm{bad}}_{\mathrm{mod}} \times_{\mathbb{V}_{\mathrm{mod}}} \underline{\mathbb{V}} \ \subseteq \ \underline{\mathbb{V}}, \quad \mathbb{V}^{\mathrm{good}}_{\mathrm{mod}} \stackrel{\mathrm{def}}{=} \mathbb{V}_{\mathrm{mod}} \ \setminus \ \mathbb{V}^{\mathrm{bad}}_{\mathrm{mod}}, \quad \underline{\mathbb{V}}^{\mathrm{good}} \stackrel{\mathrm{def}}{=} \underline{\mathbb{V}} \ \setminus \ \underline{\mathbb{V}}^{\mathrm{bad}}$$

and apply the superscripts "non" and "arc" to $\underline{\mathbb{V}}$, $\mathbb{V}_{\mathrm{mod}}$, and $\mathbb{V}(-)$ to denote the subsets of nonarchimedean and archimedean valuations, respectively. The data listed above determines, up to K-isomorphism [cf. [IUTchI], Remark 3.1.3], a finite étale covering $\underline{C}_K \to C_K$ of degree l such that the base-changed covering

$$\underline{X}_K \quad \stackrel{\mathrm{def}}{=} \quad \underline{C}_K \times_{C_F} X_F \quad \to \quad X_K \quad \stackrel{\mathrm{def}}{=} \quad X_F \times_F K$$

arises from a rank one quotient $E_K[l] \to Q \ (\cong \mathbb{Z}/l\mathbb{Z})$ of the module $E_K[l]$ of l-torsion points of $E_K(K)$ [where we write $E_K \stackrel{\text{def}}{=} E_F \times_F K$] which, at $\underline{v} \in \underline{\mathbb{V}}^{\text{bad}}$, restricts to the quotient arising from coverings of the dual graph of the special fiber.

(ii) The log-theta-lattice: The log-theta-lattice, various versions of which are defined in [IUTchIII] [cf. [IUTchIII], Definitions 1.4; 3.8, (iii)], is a [highly non-commutative! two-dimensional diagram that consists of three types of components, namely, \bullet 's, \uparrow 's, and \rightarrow 's [cf. the portion of Fig. 3.6 below that lies to the *left* of the " \supseteq "]. Each " \bullet " in Fig. 3.6 represents a $\Theta^{\pm \text{ell}}$ **NF-Hodge the**ater, which may be thought of as a sort of miniature model of the conventional arithmetic geometry surrounding the given initial Θ -data. Each vertical arrow "\" in Fig. 3.6 represents a log-link, i.e., a certain type of gluing between various portions of the $\Theta^{\pm \text{ell}}$ NF-Hodge theaters that constitute the domain and codomain of the arrow. Each horizontal arrow " \rightarrow " in Fig. 3.6 represents a Θ -link [various versions of which are defined in [IUTchI], [IUTchII], [IUTchIII], i.e., another type of gluing between various portions of the $\Theta^{\pm \text{ell}}$ NF-Hodge theaters that constitute the domain and codomain of the arrow. The portion of the log-theta-lattice that is ultimately actually used to prove the main results of inter-universal Teichmüller theory is shown in the portion of Fig. 3.6 — i.e., a sort of "infinite letter H" that lies to the right of the " \supseteq ". On the other hand, the significance of considering the entire log-theta-lattice may be seen in the fact that — unlike the portion of Fig. 3.6 that lies to the right of the " \supseteq "! —

the [entire] log-theta-lattice is **symmetric**, up to unique isomorphism, with respect to arbitrary **horizontal** and **vertical translations**.

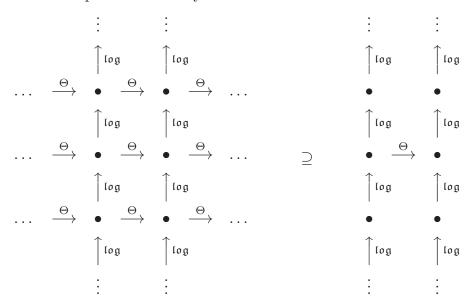

Fig. 3.6: The entire log-theta-lattice and the portion that is actually used

Various objects constructed from the •'s of the log-theta-lattice will be referred to as **horizontally coric** if they are *invariant* with respect to arbitrary *horizontal* translations, as **vertically coric** if they are *invariant* with respect to arbitrary *vertical* translations, and as **bi-coric** if they are *both* horizontally and vertically coric. In this context, we observe that — unlike any *finite* portion of a *vertical line* of the log-theta-lattice! —

each [infinite!] vertical line of the log-theta-lattice is **symmetric**, up to unique isomorphism, with respect to arbitrary **vertical translations**.

As we shall we see in $\S 3.6$, (iv), below, this is precisely why [cf. the portion of Fig. 3.6 that lies to the *right* of the " \supseteq "] it will ultimately be necessary to work with the *entire infinite vertical lines* of the log-theta-lattice [i.e., as opposed to with some finite portion of such a vertical line]. Finally, we remark that

the **two dimensions** of the log-theta-lattice may be thought of as corresponding to the **two underlying combinatorial dimensions** of a **ring** [cf. the discussion of these two dimensions in the case of NF's and MLF's in §2.11], i.e., to **addition** and **multiplication**.

Indeed, the Θ -link only involves the multiplicative structure of the rings involved and, at an extremely rough level, may be understood as corresponding to thinking of "numbers" as elements of the multiplicative monoid of positive integers

$$\mathbb{N}_{\geq 1} \cong \bigoplus_{p} p^{\mathbb{N}}$$

— where p ranges over the prime numbers, and \mathbb{N} denotes the additive monoid of nonnegative integers — that is to say, as elements of an abstract monoid that admits automorphisms that switch distinct prime numbers p_1 , p_2 , as well as endomorphisms given by raising to the N-th power [cf. the discussion of §2.4]. By contrast, the \log -link may be understood as corresponding to a link between, or juggling of, the

additive and multiplicative structures at the various completions of an NF that is obtained by means of the various natural logarithms defined on these completions [cf. the discussion of Example 2.12.3, (v)]. Alternatively, relative to the analogy with the **two dimensions** of an MLF, if the MLF under consideration is absolutely unramified, i.e., isomorphic to the quotient field of a ring of Witt vectors, then one may think of

- the log-link as corresponding to the Frobenius morphism in positive characteristic, i.e., to one of the two underlying combinatorial dimensions — namely, the slope zero dimension — of the MLF and of
- the Θ -link as corresponding to the mixed characteristic extension **structure** of a ring of Witt vectors, i.e., to the transition from $p^n\mathbb{Z}/p^{n+1}\mathbb{Z}$ to $p^{n-1}\mathbb{Z}/p^n\mathbb{Z}$, which may be thought of as corresponding to the other of the two underlying combinatorial dimensions — namely, the positive slope dimension — of the MLF.

We refer to [IUTchI], §I4; [IUTchIII], Introduction; [IUTchIII], Remark 1.4.1, (iii); [IUTchIII], Remark 3.12.4; [Pano], §2, for more details concerning the numerous analogies between inter-universal Teichmüller theory and various aspects of the padic theory, such as the canonical liftings that play a central role in the p-adic **Teichmüller theory** of [pOrd], [pTch].

(iii) The notion of a Frobenioid: A Frobenioid is an abstract category whose abstract categorical structure may be thought of, roughly speaking, as encoding

the theory of divisors and line bundles on various "coverings" — i.e., normalizations in various finite separable extensions of the function field — of a given normal integral scheme.

Here, the category of such "coverings" is referred to as the base category of the Frobenioid. All of the Frobenioids that play a [non-negligible] role in inter-universal Teichmüller theory are model Frobenioids [cf. [FrdI], Theorem 5.2] whose base category corresponds to "some sort of" — that is to say, possibly tempered, in the sense of [André], §4; [Semi], Example 3.10 — arithmetic fundamental group i.e., in the non-tempered case, the étale fundamental group of a normal integral scheme of finite type over some sort of "arithmetic field". In particular, all of the Frobenioids that play a [non-negligible] role in inter-universal Teichmüller theory are essentially equivalent to a collection of data as follows that satisfies certain properties:

- · a topological group, i.e., the [possibly tempered] arithmetic fundamental group;
- · for each open subgroup of the topological group, an abelian group, called the rational function monoid, i.e., since it is a category-theoretic abstraction of the multiplicative group of rational functions on the "covering" corresponding to the given open subgroup;
- · for each open subgroup of the topological group, an abelian monoid, called the divisor monoid, i.e., since it is a category-theoretic abstraction of the monoid of Weil divisors on the "covering" corresponding to the given open subgroup.

In particular, such Frobenioids may be thought of as category-theoretic abstractions of various aspects of the **multiplicative** portion of the ring structure of a normal integral scheme. We refer to §3.5 below for more remarks on the use of Frobenioids in inter-universal Teichmüller theory.

(iv) $\Theta^{\pm \text{ell}}$ NF-|Hodge theaters as "tautological solutions" to a purely The $\Theta^{\pm \text{ell}}$ NF-Hodge theater associated to a given combinatorial problem: collection of initial Θ -data as in (i) is a somewhat complicated system of Frobe**nioids** [cf. [IUTchI], Definition 6.13, (i)]. The topological group data for these Frobenioids arises from various subquotients of the [possibly tempered] arithmetic fundamental groups of the hyperbolic orbicurves discussed in (i). The rational function monoid data for these Frobenioids arises from the multiplicative groups of nonzero elements of various finite extensions of the number field F_{mod} of (i) or localizations [i.e., completions] of such NF's at valuations lying over valuations $\in \underline{\mathbb{V}}$. The divisor monoid data for these Frobenioids arises, in the case of NF's, from the monoid of effective arithmetic divisors in the sense of diophantine geometry — cf., e.g., [GenEll], §1; [FrdI], Example 6.3], possibly with real coefficients, and, in the case of localizations of NF's, from the nonnegative portion of the value group of the associated valuation, possibly tensored over \mathbb{Z} with \mathbb{R} . [In fact, at valuations in V^{bad}, an additional type of Frobenioid, called a tempered Frobenioid, also appears — cf. the discussion of §3.4, (iv); §3.5, below.] For instance, in the case of localizations at valuations $\in \mathbb{V}^{good} \cap \mathbb{V}^{non}$, one Frobenioid that appears quite frequently in inter-universal Teichmüller theory consists of data that is essentially equivalent to the data

"
$$\Pi_X \curvearrowright \mathcal{O}_{\overline{k}}^{\triangleright}$$
"

considered in Example 2.12.3, (ii). [In the case of valuations $\in \underline{\mathbb{V}}^{\mathrm{bad}}$, " Π_X " is replaced by the corresponding tempered arithmetic fundamental group; in the case of valuations $\in \underline{\mathbb{V}}^{\mathrm{arc}}$ ($\subseteq \underline{\mathbb{V}}^{\mathrm{good}}$), one applies the theory of [AbsTopIII], §2.] In general, the Frobenioids obtained by applying the operation of "passing to real coefficients" are referred to as **realified Frobenioids** [cf. [FrdI], Proposition 5.3]. The system of Frobenioids that constitutes a $\Theta^{\pm \mathrm{ell}}$ NF-Hodge theater determines, by passing to the associated system of base categories, an apparatus that is referred to as a \mathcal{D} - $\Theta^{\pm \mathrm{ell}}$ NF-Hodge theater [cf. [IUTchI], Definition 6.13, (ii)]. The purpose of considering such systems of Frobenioids lies in the goal of

reassembling the distribution of primes in the number field K [cf. the discussion of [IUTchI], Remark 4.3.1] in such a way as to render possible the construction of some sort of global version of the "Gaussian distribution"

$$\{\underline{\underline{q}}^{j^2}\}_{j=1,\dots,l^*}$$

discussed at the end of §2.4, i.e., which, a priori, is only defined at the valuations $\in \mathbb{V}(K)^{\text{non}}$ at which E_K has bad multiplicative reduction [such as, for instance, the valuations $\in \underline{\mathbb{V}}^{\text{bad}}$].

This "global version" amounts to the local and global value group portions of the data that appears in the domain portion of the Θ -link [cf. (vii) below]. The reassembling, referred to above, of the distribution of primes in the number field K was one of the fundamental motivating issues for the author in the development

of the absolute mono-anabelian geometry of [AbsTopIII], i.e., of a version of anabelian geometry that differs fundamentally from the well-known anabelian result of Neukirch-Uchida concerning absolute Galois groups of NF's [cf., e.g., [NSW], Chapter XII, $\S 2$ in [numerous ways, but, in particular, in] that its reconstruction of an NF does not depend on the distribution of primes in the NF [cf. the discussion of [IUTchI], Remarks 4.3.1, 4.3.2]. The problem, referred to above, of constructing a sort of "global Gaussian distribution" may in fact easily be seen to be

essentially equivalent to the "purely combinatorial" problem of constructing a "global multiplicative subspace" [cf. the discussion of §2.3], together with a "global canonical generator", i.e., more precisely: a one-dimensional \mathbb{F}_l -subspace of the two-dimensional \mathbb{F}_l -vector space $E_K[l]$ of l-torsion points of the elliptic curve E_K , together with a generator, well-defined up to multiplication by ± 1 , of the quotient of $E_K[l]$ by this one-dimensional \mathbb{F}_l -subspace, such that this subspace and generator *coincide*, at the valuations $\in \mathbb{V}(K)$ that lie over valuations $\in \mathbb{V}_{\text{mod}}^{\text{bad}}$, with a certain *canonical* such subspace and generator that arise from a generator [again, well-defined up to multiplication by ± 1] of the Galois group [isomorphic to \mathbb{Z}] of the well-known infinite covering of a Tate curve.

Here, we note that such a "global canonical generator" determines a bijection, which is well-defined up to multiplication by ± 1 , of the quotient referred to above with the underlying additive group of \mathbb{F}_l . In a word, the combinatorial structure of a $\Theta^{\pm \text{ell}}$ NF-Hodge theater furnishes a sort of "tautological solution" to the purely combinatorial problem referred to above by

simply ignoring the valuations $\in \mathbb{V}(K) \setminus \mathbb{V}$, for instance, by working only with Frobenioids — i.e., in effect, arithmetic divisors/line bundles — that arise from arithmetic divisors **supported** on the set of valuations $\mathbb{V} (\subset \mathbb{V}(K))$, i.e., as opposed to on the entire set $\mathbb{V}(K)$

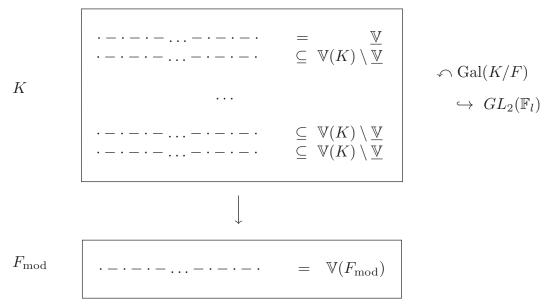

Fig. 3.7: Prime-strips as "sections" of $\operatorname{Spec}(K) \to \operatorname{Spec}(F_{\operatorname{mod}})$

[cf. the discussion of [IUTchI], Remark 4.3.1]. Here, we note that this sort of operation of discarding certain of the primes of an NF can only be performed if one **forgets** the **additive structure** of an NF [i.e., since a sum of elements of an NF that are *invertible* at a given nonempty set of primes is *no longer necessarily invertible* at those primes! — cf. [AbsTopIII], Remark 5.10.2, (iv)] and works only with **multiplicative structures**, e.g., with Frobenioids. Collections of *local data* — consisting, say, of *local Frobenioids* or *local [possibly tempered] arithmetic fundamental groups* — indexed by the elements of $\underline{\mathbb{V}}$ are referred to as **prime-strips** [cf. Fig. 3.7 above; [IUTchI], Fig. I1.2, and the surrounding discussion]. In a word, prime-strips may be thought of as a sort of **monoid-** or **Galois-theoretic** version of the classical notion of **adèles/idèles**.

(v) The symmetries of a $\Theta^{\pm \text{ell}}$ NF-Hodge theater: Once the "tautological solution" furnished by the combinatorial structure of a $\Theta^{\pm \text{ell}}$ NF-Hodge theater is applied, the quotient of $E_K[l]$ discussed in (iv) corresponds to the quotient "Q" of (i), i.e., in effect, to the set of cusps of the hyperbolic curve \underline{X}_K of (i). One may then consider additive and multiplicative symmetries

$$\mathbb{F}_l^{\times\pm} \ \stackrel{\mathrm{def}}{=} \ \mathbb{F}_l \ \rtimes \ \{\pm 1\}, \quad \mathbb{F}_l^{*} \ \stackrel{\mathrm{def}}{=} \ \mathbb{F}_l^{\times}/\{\pm 1\}$$

— where $\mathbb{F}_l^{\times} \stackrel{\text{def}}{=} \mathbb{F}_l \setminus \{0\}$, and ± 1 acts on \mathbb{F}_l in the usual way — on the *underlying* sets

$$\mathbb{F}_l = \{-l^*, \dots, -1, 0, 1, \dots, l^*\}, \quad \mathbb{F}_l^* = \{1, \dots, l^*\}$$

— where $l^* \stackrel{\text{def}}{=} (l-1)/2$; the numbers listed in the above display are to be regarded modulo l; we think of \mathbb{F}_l as the quotient Q [i.e., the set of cusps of \underline{X}_K and its localizations at valuations $\in \underline{\mathbb{V}}$] discussed above and of \mathbb{F}_l^* as a certain subquotient of Q. Here, we remark that this interpretation of the quotient Q as a set of cusps of \underline{X}_K induces a natural outer isomorphism of $\mathbb{F}_l^{\times \pm}$ with the group of "geometric automorphisms"

$$\operatorname{Aut}_K(\underline{X}_K)$$

[i.e., the group of K-automorphisms of the K-scheme \underline{X}_K], as well as a *natural* isomorphism of \mathbb{F}_l^* with a certain quotient of the image of the group of "arithmetic automorphisms"

$$\operatorname{Aut}(\underline{C}_K) \hookrightarrow \operatorname{Gal}(K/F_{\operatorname{mod}})$$

[i.e., the group of automorphisms of the algebraic stack \underline{C}_K , which, as is easily verified, maps injectively into the Galois group $\operatorname{Gal}(K/F_{\operatorname{mod}})$]. The **combinatorial** structure of a $\Theta^{\pm \operatorname{ell}}$ NF-Hodge theater may then be summarized as

the system of Frobenioids obtained by localizing and gluing together various Frobenioids or [possibly tempered] arithmetic fundamental groups associated to \underline{X}_K and \underline{C}_K in the fashion prescribed by the **combinatorial** recipe

$$\mathbb{F}_{l}^{\times \pm} \curvearrowright \mathbb{F}_{l} \supseteq \mathbb{F}_{l}^{\times} \twoheadrightarrow \mathbb{F}_{l}^{*} \curvearrowleft \mathbb{F}_{l}^{*}$$

— cf. Fig. 3.8 below.

$$\begin{bmatrix} -l^{*} < \dots < -1 < 0 \\ < 1 < \dots < l^{*} \end{bmatrix}$$

$$\uparrow \qquad \Rightarrow \text{ glue! } \Leftarrow \qquad \uparrow$$

$$\begin{cases} \frac{\pm 1}{2} \\ \begin{pmatrix} -l^{*} < \dots < -1 < 0 \\ < 1 < \dots < l^{*} \end{pmatrix}$$

$$\downarrow \qquad \qquad \downarrow$$

$$\pm \rightarrow \pm \qquad \qquad \downarrow$$

$$\uparrow \stackrel{\mathbb{F}^{\times \pm}}{2} \qquad \qquad \uparrow$$

$$\pm \leftarrow \pm \qquad \qquad \vdots$$
...cf. ordinary monodromy, additive symmetries!
$$\begin{bmatrix} 1 < \dots \\ < l^{*} \end{bmatrix}$$

$$\begin{pmatrix} 1 < \dots \\ < l^{*} \end{pmatrix}$$

$$\downarrow \qquad \qquad \downarrow$$

$$* \rightarrow *$$

$$\uparrow \stackrel{\mathbb{F}^{*}}{2} \downarrow$$

$$* \leftarrow *$$
...cf. supersingular monodromy, toral symmetries!

Fig. 3.8: The *combinatorial structure* of a $\Theta^{\pm \text{ell}}$ NF-Hodge theater: a bookkeeping apparatus for *l-torsion points*

Here, we remark that, in Fig. 3.8:

- · the squares with actions by $\mathbb{F}_l^{\times \pm}$ and \mathbb{F}_l^* correspond to Frobenioids or arithmetic fundamental groups that arise from \underline{X}_K and \underline{C}_K , respectively;
- · each of the elements of \mathbb{F}_l or \mathbb{F}_l^* that appears in parentheses "(...)" corresponds to a **single prime-strip**;
- · each portion enclosed in brackets "[...]" corresponds to a **single prime- strip**;
- the arrows " \uparrow " correspond to the relation of passing from the various **individual elements** of \mathbb{F}_l or \mathbb{F}_l^* [i.e., one prime-strip for each individual element] to the **entire set** \mathbb{F}_l or \mathbb{F}_l^* [i.e., one prime-strip for the entire set];
- · the arrows " \Downarrow " correspond to the relation of regarding the set of elements in parentheses " (\dots) " with **fixed labels** as the underlying set of a set equipped with an **action** by $\mathbb{F}_l^{\times \pm}$ or \mathbb{F}_l^* ;
- · the gluing is the gluing prescribed by the surjection $\mathbb{F}_l \supseteq \mathbb{F}_l^{\times} \twoheadrightarrow \mathbb{F}_l^{*}$.

In this context, it is important to keep in mind that

the $\mathbb{F}_l^{\times \pm}$ - and \mathbb{F}_l^* -symmetries of a $\Theta^{\pm \text{ell}}$ NF-Hodge theater play a fundamental role in the **Kummer-theoretic** aspects of inter-universal Teichmüller theory that are discussed in §3.6 below.

As remarked in §2.4, the $\mathbb{F}_l^{\times\pm}$ - and \mathbb{F}_l^* -symmetries of a $\Theta^{\pm \mathrm{ell}}$ NF-Hodge theater may be thought of as corresponding, respectively, to the **additive** and **multiplicative/toral symmetries** of the *classical upper half-plane* [cf. [IUTchI], Remark 6.12.3, (iii); [BogIUT], for more details]. Alternatively, the $\mathbb{F}_l^{\times\pm}$ - and \mathbb{F}_l^* -symmetries of a $\Theta^{\pm \mathrm{ell}}$ NF-Hodge theater may be thought of as corresponding, respectively, to the [unipotent] ordinary and [toral] supersingular monodromy

— i.e., put another way, to the well-known structure of the **p-Hecke correspondence** — that occurs in the well-known classical p-adic theory surrounding the **moduli stack of elliptic curves** over the p-adic integers \mathbb{Z}_p [cf. the discussion of [IUTchI], Remark 4.3.1; [IUTchII], Remark 4.11.4, (iii), (c)].

(vi) <u>log-links</u>: Each vertical arrow

of the log-theta-lattice relates the various copies of

"
$$\Pi_X \curvearrowright \mathcal{O}_{\overline{k}}^{\triangleright}$$
"

[cf. the discussion at the beginning of (iv)] that lie in the prime-strips of the domain $\Theta^{\pm \mathrm{ell}}$ NF-Hodge theater "•" of the \log -link to the corresponding copy of " $\Pi_X \curvearrowright \mathcal{O}_k^{\trianglerighteq}$ " that lies in a prime-strip of the codomain $\Theta^{\pm \mathrm{ell}}$ NF-Hodge theater "•" of the \log -link in the fashion prescribed by the arrow " \log " of the diagram of Example 2.12.3, (iii) [with suitable modifications involving tempered arithmetic fundamental groups at the valuations $\in \underline{\mathbb{V}}^{\mathrm{bad}}$ or the theory of [AbsTopIII], §2, at the valuations $\in \underline{\mathbb{V}}^{\mathrm{arc}}$ ($\subseteq \underline{\mathbb{V}}^{\mathrm{good}}$)]. In particular, the \log -link may be thought of as "lying over" an **isomorphism** between the respective copies of " Π_X " which is **indeterminate** since [cf. the discussion of §2.10; the discussion at the end of Example 2.12.3, (ii)] the two copies of " Π_X " must be regarded as distinct abstract topological groups. Put another way, from the point of view of the discussion at the beginning of (iv),

the log-link induces an **indeterminate isomorphism** between the \mathcal{D} - $\Theta^{\pm \mathrm{ell}}$ NF-Hodge theaters associated to the $\Theta^{\pm \mathrm{ell}}$ NF-Hodge theaters " \bullet " in the *domain* and *codomain* of the log-link, that is to say, these \mathcal{D} - $\Theta^{\pm \mathrm{ell}}$ NF-Hodge theaters associated to the \bullet 's of the log-theta-lattice are **vertically coric** [cf. [IUTchIII], Theorem 1.5, (i)].

Now recall from Example 2.12.3, (i), that each abstract topological group " Π_X " may be regarded as the *input data* for a **functorial algorithm** that allows one to reconstruct the base field [in this case an MLF] of the hyperbolic curve "X". Put another way, from the point of view of the terminology discussed in §2.7, (vii), each copy of " Π_X " may be regarded as an arithmetic holomorphic structure on the quotient group " $\Pi_X \to G_k$ " associated to Π_X [cf. the discussion of Example 2.12.3, (i)]. Indeed, this is precisely the point of the analogy between the fundamental prototypical examples — i.e., Examples 3.2.1, 3.2.2 — of the phenomenon of multiradiality. The various "X's" that occur in a $\Theta^{\pm \text{ell}}$ NF-Hodge theater are certain finite étale coverings of localizations of the hyperbolic curve \underline{X}_K at various valuations $\in \underline{\mathbb{V}}$. These finite étale coverings are hyperbolic curves over $K_{\underline{v}}$ which are denoted $\underline{\underline{X}}_{\underline{v}}$ in the case of $\underline{v} \in \underline{\mathbb{V}}^{\mathrm{bad}}$ and $\underline{\underline{X}}_{\underline{v}}$ in the case of $\underline{v} \in \underline{\mathbb{V}}^{\mathrm{good}}$ [cf. [IUTchI], Definition 3.1, (e), (f)]. On the other hand, we recall from [AbsTopIII], Theorem 1.9 [cf. also [AbsTopIII], Remark 1.9.2], that this functorial algorithm may also be applied to the hyperbolic orbicurves \underline{X}_K , \underline{C}_K , or $C_{F_{\text{mod}}}$, i.e., whose base fields are NF's, in a fashion that is functorial [cf. the discussion of [IUTchI], Remarks 3.1.2, 4.3.2 with respect to passing to finite étale coverings, as well as with

respect to **localization** at valuations of $\in \underline{\mathbb{V}}$ [cf. also the theory of [AbsTopIII], §2, in the case of valuations $\in \mathbb{V}^{arc}$]. That is to say, in summary,

the various [possibly tempered, in the case of valuations $\in \underline{\mathbb{V}}^{\mathrm{bad}}$] arithmetic fundamental groups of finite étale coverings of $C_{F_{\mathrm{mod}}}$ [such as \underline{X}_K , \underline{C}_K , or $C_{F_{\mathrm{mod}}}$ itself] and their localizations at valuations $\in \underline{\mathbb{V}}$ that appear in a $\Theta^{\pm \mathrm{ell}}$ NF-Hodge theater may be regarded as abstract representations of the arithmetic holomorphic structure [i.e., ring structure—cf. the discussion of §2.7, (vii)] of the various base fields of these hyperbolic orbicurves.

Moreover, this state of affairs motivates the point of view that

the various localizations and gluings that occur in the structure of a single $\Theta^{\pm \text{ell}}$ NF-Hodge theater [cf. Fig. 3.8] or, as just described, in the structure of a log-link [i.e., a vertical arrow of the log-theta-lattice — cf. Fig. 3.6] may be thought of as arithmetic analytic continuations between various NF's along the various gluings of prime-strips that occur [cf. the discussion of [IUTchI], Remarks 4.3.1, 4.3.2, 4.3.3, 5.1.4].

In this context, it is of interest to observe that, at a technical level, these arithmetic analytic continuations are achieved by applying the mono-anabelian theory of [AbsTopIII], §1 [or, in the case of archimedean valuations, the theory of [AbsTopIII], §2]. Moreover, this mono-anabelian theory of [AbsTopIII], §1, is, in essence, an elementary consequence of the theory of **Belyi cuspidalizations** developed in [AbsTopII], §3 [cf. [AbsTopIII], Remark 1.11.3]. Here, we recall that the term cuspidalization refers to a functorial algorithm in the arithmetic fundamental group of a hyperbolic curve for reconstructing the arithmetic fundamental group of some dense open subscheme of the hyperbolic curve. In particular, by considering Kummer classes of rational functions [cf. the discussion of Example 2.13.1, (i)],

cuspidalization may be thought of as a sort of "equivalence" between the function theory on a hyperbolic curve and the function theory on a dense open subscheme of the hyperbolic curve — a formulation that is very formally reminiscent of the classical notion of analytic continuation.

The **Belyi cuspidalizations** developed in [AbsTopII], §3, are achieved as a formal consequence of the *elementary observation* that

any "sufficiently small" **dense open subscheme** U of the hyperbolic curve P given by removing three points from the projective line may be regarded — via the use of a suitable **Belyi map!** — as a **finite étale covering** of P; in particular, the arithmetic fundamental group of U may be recovered from the arithmetic fundamental group of P by considering a *suitable open subgroup* of the arithmetic fundamental group of P [cf. [AbsTopII], Example 3.6; [AbsTopII], Corollaries 3.7, 3.8, for more details].

This state of affairs is all the more fascinating in that the well-known construction of Belyi maps via an induction on the degree over \mathbb{Q} of the ramification locus of certain rational maps between two projective lines is [cf. the discussion of [IUTchI], Remark 5.1.4] is highly reminiscent of the well-known **Schwarz lemma** of elementary complex analysis, i.e., to the effect that the absolute value, relative to the

respective Poincaré metrics, of the derivative at any point of a holomorphic map between copies of the unit disc is ≤ 1 .

(vii) Θ -links: Various versions of the " Θ -link" are defined in [IUTchI], [IUTchII], [IUTchIII] — cf. [IUTchI], Corollary 3.7, (i); [IUTchII], Corollary 4.10, (iii); [IUTchIII], Definition 3.8, (ii). In the present paper, we shall primarily be interested in the version of [IUTchIII], Definition 3.8, (ii); the versions of [IUTchIII], Corollary 4.10, (iii), are partially simplified versions of the version that one is ultimately interested in [i.e., the version of [IUTchIII], Definition 3.8, (ii)], while the version of [IUTchI], Corollary 3.7, (i), is an even more drastically simplified version of these partially simplified versions. The Θ -link may be understood, roughly speaking, as a realization of the version of the assignment " $q \mapsto q^N$ " considered in the final portion of the discussion of §2.4, i.e., the assignment

$$"\underline{\underline{q}} \mapsto \{\underline{\underline{q}}^{j^2}\}_{j=1,\dots,l*}"$$

given by taking a sort of symmetrized average as "N" varies over the values j^2 , for $j = 1, ..., l^*$. At a more technical level, the Θ -link

$$ullet$$
 $\xrightarrow{\Theta}$ $ullet$

is a **gluing** between two $\Theta^{\pm \text{ell}}$ NF-Hodge theaters "•", via an **indeterminate** [cf. the discussion of §2.10] **isomorphism** between certain *gluing data* arising from the *domain* $\Theta^{\pm \text{ell}}$ NF-Hodge theater "•" and certain *gluing data* arising from the *codomain* $\Theta^{\pm \text{ell}}$ NF-Hodge theater "•". The **gluing data** that arises from the **domain** "•" of the Θ -link is as follows:

 (a^{Θ}) [Local] unit group portion: Consider, in the notation of §2.11, §2.12 [cf., especially, Example 2.12.3, (iv)], the ind-topological monoid equipped with an action by a topological group $G_k \curvearrowright \mathcal{O}_{\overline{k}}^{\times \mu}$, where we note that $\mathcal{O}_{\overline{k}}^{\times \mu}$ is a \mathbb{Q}_p -vector space. Observe that for each open subgroup $H \subseteq G_k$, which determines a subfield $\overline{k}^H \subseteq \overline{k}$ of H-invariants of \overline{k} , the image of $\mathcal{O}_{\overline{k}}^{\times \mu}$ in $\mathcal{O}_{\overline{k}}^{\times \mu}$ determines an integral structure, or "lattice" [i.e., a finite free \mathbb{Z}_p -module], in the \mathbb{Q}_p -vector subspace of H-invariants $(\mathcal{O}_{\overline{k}}^{\times \mu})^H$ of $\mathcal{O}_{\overline{k}}^{\times \mu}$. [Here, we note that the theory of the p-adic logarithm determines a natural isomorphism between this subspace and the \mathbb{Q}_p -vector \overline{k}^H .] For each $\underline{v} \in \underline{\mathbb{V}}^{\text{non}}$, we take the unit group portion data at \underline{v} , to be this data

$$(G_k \curvearrowright \mathcal{O}_{\overline{k}}^{\times \mu}, \{\mathcal{O}_{\overline{k}^H}^{\times \mu} \subseteq (\mathcal{O}_{\overline{k}}^{\times \mu})^H\}_H)$$

- i.e., which we regard as an ind-topological monoid equipped with an action by a topological group, together with, for each open subgroup of the topological group, an integral structure in the case $k \stackrel{\text{def}}{=} K_{\underline{v}}$. When $k = K_{\underline{v}}$, we shall write $G_{\underline{v}} \stackrel{\text{def}}{=} G_k$. An analogous construction may be performed for $\underline{v} \in \underline{\mathbb{V}}^{\text{arc}}$.
- (b^{Θ}) Local value group portion: At each $\underline{v} \in \underline{\mathbb{V}}^{\text{bad}}$, we take the *local* value group portion data at \underline{v} to be the formal monoid [abstractly isomorphic to the monoid \mathbb{N}] generated by

$$\{\underline{\underline{q}}^{j^2}\}_{j=1,...,l}$$
*

- i.e., where $\underline{q}_{\underline{v}} \in \mathcal{O}_{K_{\underline{v}}}^{\triangleright}$ is a 2l-th root of the q-parameter $q_{\underline{v}}$ of the elliptic curve E_K at \underline{v} ; the data of the above display is regarded as a collection of elements of $\mathcal{O}_{K_{\underline{v}}}^{\triangleright}$ indexed by the elements of \mathbb{F}_l^* ; each element of this collection is well-defined up to multiplication by a 2l-th root of unity. An analogous, though somewhat more formal, construction may be performed for $\underline{v} \in \underline{\mathbb{V}}^{\mathrm{good}}$.
- Global value group portion: Observe that each of the local formal monoids [say, for simplicity, at $\underline{v} \in \underline{\mathbb{V}}^{\text{bad}}$] of (b^{Θ}) may be realified. That is to say that, the corresponding realified monoid is simply the monoid of $\mathbb{R}_{\geq 0}$ -multiples [i.e., nonnegative real multiples] of the image of the given monoid $[\cong \mathbb{N}]$ inside the tensor product $\otimes_{\mathbb{Z}} \mathbb{R}$ of the groupification $[\cong \mathbb{Z}]$ of this given monoid. Note, moreover, that the product formula of elementary algebraic number theory yields a natural notion of "finite collections of elements of the groupifications $[\cong \mathbb{R}]$ of these realified monoids at $\underline{v} \in \underline{\mathbb{V}}$ whose sum = 0". This data, consisting of a realified monoid at each $\underline{v} \in \underline{\mathbb{V}}$, together with a collection of "product formula relations", determines a global realified Frobenioid. We take the global value group portion data to be this global realified Frobenioid.

The gluing data that arises from the codomain of the Θ -link is as follows:

- (a^q) [Local] unit group portion: For each $\underline{v} \in \underline{\mathbb{V}}$, we take the unit group portion data at \underline{v} to be the analogous data, i.e., this time constructed from the codomain " \bullet " of the Θ -link, to the data of (a^{Θ}).
- (b^q) <u>Local value group portion</u>: At each $\underline{v} \in \underline{\mathbb{V}}^{bad}$, we take the *local value group portion data at* \underline{v} to be the *formal monoid* [abstractly isomorphic to the monoid \mathbb{N}] generated by

 $\underline{\underline{q}}_{v}$

- i.e., where we apply the notational conventions of (b^{Θ}) . An analogous, though somewhat *more formal*, construction may be performed for $\underline{v} \in \underline{\mathbb{V}}^{good}$.
- (c^q) Global value group portion: We take the global value group portion data to be the global realified Frobenioid [cf. the data of (c^{Θ})] determined by the realifications of the local formal monoids of (b^q) at $\underline{v} \in \underline{\mathbb{V}}$, together with a naturally determined collection of "product formula relations".

In fact, the above description is *slightly inaccurate* in a number of ways: for instance, in [IUTchI], [IUTchII], the data of (a^{Θ}) , (b^{Θ}) , (c^{Θ}) , (a^q) , (b^q) , (c^q) are constructed in a somewhat more **intrinsic** fashion directly from the various **Frobenioids** [and other data] that constitute the $\Theta^{\pm \text{ell}}$ NF-Hodge theater "•" under consideration. This sort of *intrinsic* construction exhibits, in a very natural fashion,

the ind-topological monoids " $\mathcal{O}_{\overline{k}}^{\times \boldsymbol{\mu}}$ " of (a^{Θ}) and (a^q) , the local formal monoids of (b^{Θ}) and (b^q) , and the global realified Frobenioids of (c^{Θ}) and (c^q) as **Frobenius-like** objects.

By contrast,

the topological groups " G_k " of (a^{Θ}) and (a^q) are **étale-like** objects.

In this context, it is useful to note — cf. the discussion of the **vertical coricity** of \mathcal{D} - $\Theta^{\pm \text{ell}}$ NF-Hodge theaters in (vi) — that

the unit group portion data of (a^{Θ}) , (a^q) is horizontally coric [cf. [IUTchIII], Theorem 1.5, (ii)], while the portion of this data constituted by the **topological group** " G_k " is **bi-coric** [cf. [IUTchIII], Theorem 1.5, (iii)].

Indeed,

one way to think of **Frobenius-like** structures, in the context of the log-theta-lattice, is as structures that, at least *a priori*, are **confined to** — i.e., at least *a priori*, are **only defined in** — a **fixed** $\Theta^{\pm \text{ell}}$ NF-Hodge theater "•" of the log-theta-lattice.

Thus, in summary, the

 Θ -link induces an **isomorphism** of the **unit group portion data** of (a^{Θ}) , (a^q) , on the one hand, and a **dilation**, by a *factor* given by a sort of symmetrized average of the j^2 , for $j = 1, \ldots, l^*$, of the **local** and **global** value group data of (b^{Θ}) , (c^{Θ}) , (b^q) , (c^q) , on the other.

The object, well-defined up to isomorphism, of the global realified Frobenioid of (c^{Θ}) determined by the unique collection of generators of the local formal monoids of (b^{Θ}) at $\underline{v} \in \underline{\mathbb{V}}^{\text{bad}}$ will be referred to as the Θ -pilot object [cf. [IUTchI], Definition 3.8, (i)]. In a similar vein, the object, well-defined up to isomorphism, of the global realified Frobenioid of (c^q) determined by the unique collection of generators of the local formal monoids of (b^q) at $\underline{v} \in \underline{\mathbb{V}}^{\text{bad}}$ will be referred to as the q-pilot object [cf. [IUTchI], Definition 3.8, (i)]. The Θ - and q-pilot objects play a central role in the main results of inter-universal Teichmüller theory, which are the main topic of §3.7 below.

§3.4. Kummer theory and multiradial decouplings/cyclotomic rigidity: The first main result of inter-universal Teichmüller theory [cf. §3.7, (i)] consists of a multiradial representation of the Θ -pilot objects discussed in §3.3, (vii). Relative to the general discussion of multiradiality in §3.1, this multiradiality may be understood as being with respect to the radial algorithm

$$(a^{\Theta}), (b^{\Theta}), (c^{\Theta}) \mapsto (a^{\Theta})$$

that associates to the gluing data in the domain of the Θ -link the horizontally coric unit group portion of this data [cf. the discussion of §3.3, (vii)]. The construction of this multiradial representation of Θ -pilot objects consists of two steps. The first step, which we discuss in detail in the present §3.4, is the construction of multiradial cyclotomic rigidity and decoupling algorithms for certain special types of functions on the hyperbolic curves under consideration. The second step, which we discuss in detail in §3.6 below, concerns the Galois evaluation at certain special points — i.e., evaluation via Galois sections of arithmetic fundamental groups

— of these functions to obtain certain **special values** that act on **processions** of **log-shells**.

(i) The essential role of Kummer theory: We begin with the fundamental observation that, despite the fact, for $\Box \in \{\Theta, q\}$, the construction of the data (a^{\Box}) (respectively, (b^{\Box}) ; (c^{\Box})) depends quite essentially on whether $\Box = \Theta$ or $\Box = q$, the indeterminate gluing isomorphism that constitutes a Θ -link exists — i.e., the data (a^{Θ}) (respectively, (b^{Θ}) ; (c^{Θ})) is indeed isomorphic to the data (a^q) (respectively, (b^q) ; (c^q)) — precisely as a consequence of the fact that we regard the [ind-topological] monoids that occur in this data as abstract [ind-topological] monoids that are not equipped with the auxiliary data of how these [ind-topological] monoids "happen to be constructed". That is to say, the inclusion of such auxiliary data would render the corresponding portions of data in the domain and codomain of the Θ -link non-isomorphic! Such abstract [ind-topological] monoids are a sort of prototypical example of the notion of a Frobenius-like structure [cf. [IUTchIV], Example 3.6, (iii)]. A similar observation applies to the copies of " $\mathcal{O}_k^{\triangleright}$ " that occur in the discussion of the log-link in §3.3, (vi). Thus, in summary,

it is precisely by working with **Frobenius-like structures** such as abstract [ind-topological] monoids or abstract [global realified] Frobenioids that we are able to construct the **non-ring/scheme-theoretic gluing** isomorphisms [i.e., "non-ring/scheme-theoretic" in the sense that they do not arise from morphisms of rings/schemes! of the log- and Θ -links of §3.3, (vi), (vii) [cf. the discussion of [IUTchII], Remark 3.6.2, (ii)].

By contrast,

étale-like structures such as the " G_k 's" of (a^{Θ}) and (a^q) [cf. §3.3, (vii)] or the " Π_X 's" of §3.3, (vi), will be used to compute various portions of the ring/scheme theory on the *opposite side* of a log- or Θ-link via the technique of mono-anabelian transport, as discussed in §2.7, §2.9, i.e., by determining the sort of indeterminacies that one must admit in order to render the two systems of Kummer theories — which, we recall, are applied in order to relate Frobenius-like structures to corresponding étale-like structures — in the *domain* and *codomain* of the log- or Θ-link compatible with simultaneous execution.

Here, we recall that Kummer classes are obtained, in essence, by considering cohomology classes that arise from the action of various Galois or arithmetic fundamental groups on the various roots of elements of an abstract monoid [cf. Examples 2.6.1, (iii); 2.12.1, (i); 2.13.1, (i)]. Thus, the key step in rendering such Kummer classes independent of any Frobenius-like structures lies in the algorithmic construction of a cyclotomic rigidity isomorphism between the group of torsion elements of the abstract monoid under consideration and some sort of étale-like cyclotome, i.e., that is constructed directly from the Galois or arithmetic fundamental group under consideration [cf. the isomorphism " λ " of Example 2.6.1, (iii), (iv); the isomorphism " $\rho_{\mu_{\overline{k}}}$ " of Example 2.12.1, (i), (ii), (iv); the isomorphism " λ " of Example 2.13.1, (i), (ii)]. On the other hand, let us observe, relative to the multiradiality mentioned at the beginning of the present §3.4, that the coric data " $G_k \curvearrowright \mathcal{O}_{\overline{k}}^{\times \mu}$ " admits a [nontrivial!] natural action by $\widehat{\mathbb{Z}}^{\times}$

$$\mathcal{O}_{\overline{h}}^{\times \mu} \curvearrowleft \widehat{\mathbb{Z}}^{\times}$$

[i.e., which is G_k -equivariant and compatible with the various integral structures that appear in the coric data] that lifts to a natural $\widehat{\mathbb{Z}}^{\times}$ -action on $\mathcal{O}_{\overline{k}}^{\times}$ [cf. Example 2.12.2, (i)]. This $\widehat{\mathbb{Z}}^{\times}$ -action induces a trivial action of $\widehat{\mathbb{Z}}^{\times}$ on G_k [hence also on $\mu_{\overline{k}}(G_k)$], but a nontrivial action of $\widehat{\mathbb{Z}}^{\times}$ on $\mu_{\overline{k}}$. In particular, this $\widehat{\mathbb{Z}}^{\times}$ -action on $\mathcal{O}_{\overline{k}}^{\times}$ is manifestly incompatible with the cyclotomic rigidity isomorphism

$$\rho_{\boldsymbol{\mu}_{\overline{k}}}: \boldsymbol{\mu}_{\overline{k}} \stackrel{\sim}{\to} \boldsymbol{\mu}_{\overline{k}}(G_k)$$

that was functorially constructed in Example 2.12.1, (ii), hence, in light of the functoriality of this construction, does not extend to an action of $\widehat{\mathbb{Z}}^{\times}$ on $\mathcal{O}_{\overline{k}}^{\triangleright}$. That is to say,

the naive approach just discussed to **cyclotomic rigidity isomorphisms** via the functorial construction of Example 2.12.1, (ii), is **incompatible** with the requirement of **multiradiality**, i.e., of the existence of *liftings* of arbitrary morphisms between collections of *coric data*.

This discussion motivates the following approach, which is *fundamental* to interuniversal Teichmüller theory [cf. the discussion of [IUTchIII], Remark 2.2.1, (iii); [IUTchIII], Remark 2.2.2]:

in order to obtain multiradial cyclotomic rigidity isomorphisms for the local and global value group data (b^{Θ}) and (c^{Θ}) , it is necessary to somehow decouple this data (b^{Θ}) and (c^{Θ}) from the unit group data of (a^{Θ}) .

This decoupling is achieved in inter-universal Teichmüller theory by working with certain special types of functions, as described in (ii), (iii), (iv), below.

(ii) Multiradial decouplings/cyclotomic rigidity for κ -coric rational functions: The global realified Frobenioids of (c^{Θ}) may be interpreted as "realifications" of certain categories of $[l^*$ -tuples, indexed by $j = 1, \ldots, l^*$, of arithmetic line bundles on the number field F_{mod} . The ring structure — i.e., both the additive " \boxplus " and multiplicative " \boxtimes " structures — of copies of this number field F_{mod} is applied, ultimately, in inter-universal Teichmüller theory, in order to relate these global realified Frobenioids of (c^{Θ}) , which are, in essence, a multiplicative notion, to the interpretation of arithmetic line bundles in terms of log-shells, which are modules, i.e., whose group law in written additively [cf. [IUTchIII], Remarks 3.6.2, 3.10.1] — an interpretation with respect to which global arithmetic degrees correspond to log-volumes of certain regions inside the various log-shells at each $\underline{v} \in \underline{\mathbb{V}}$ [cf. the discussion of §2.2]. Thus, in summary,

the essential structure of interest that gives rise to the data of (c^{Θ}) consists of copies of the **number field** F_{mod} indexed by $j = 1, ..., l^*$.

In particular, the **Kummer theory** [cf. the discussion of (i)!] concerning the data of (c^{Θ}) revolves around the Kummer theory of such copies of the number field F_{mod} . As discussed at the beginning of the present §3.4, elements of such copies of F_{mod} will be constructed as special values at certain special points of certain special types of functions. Here, it is perhaps of interest to recall that

this approach to constructing elements of the base field [in this case, the number field F_{mod}] of a hyperbolic curve — i.e., by evaluating Kummer classes of rational functions on the hyperbolic curve at certain special points — is precisely the approach that is in fact applied in the monoanabelian reconstruction algorithms discussed in [AbsTopIII], §1.

As discussed at the beginning of the present §3.4 [cf. also the discussion of (i)], the first step in the construction of multiradial representations of Θ -pilot objects to be discussed in §3.7, (i), consists of formulating the **Kummer theory** of suitable special types of rational functions in such a way that we obtain **multiradial** cyclotomic rigidity isomorphisms that involve a decoupling of this Kummer theory for rational functions from the unit group data of (a^{Θ}) . In the present case, i.e., which revolves around the construction of copies of F_{mod} ,

the desired formulation of Kummer theory is achieved by considering a certain subset — called the **pseudo-monoid of** κ -coric rational functions [cf. [IUTchI], Remark 3.1.7, (i), (ii)] — of the group [i.e., multiplicative monoid] " K_X^{\times} " considered in Example 2.13.1, in the case where the hyperbolic curve "X" is taken to be the hyperbolic curve \underline{X}_K of §3.3, (i) [cf. [IUTchI], Remark 3.1.2, (ii)].

Recall the hyperbolic orbicurve $C_{F_{\text{mod}}}$ discussed in §3.3, (i). Write $|C_{F_{\text{mod}}}|$ for the coarse space $|C_{F_{\text{mod}}}|$ associated to $C_{F_{\text{mod}}}$. Here, it is useful to recall the well-known fact that $|C_{F_{\text{mod}}}|$ is isomorphic to the affine line over L. We shall refer to the points of the compactification of $|C_{F_{\text{mod}}}|$ that arise from the 2-torsion points of the elliptic curve E_F other than the origin as strictly critical. A κ -coric rational function is a rational function on $|C_{F_{\text{mod}}}|$ that

restricts to a root of unity at each strictly critical point of $|C_{F_{\text{mod}}}|$

and, moreover, satisfies certain other [somewhat less essential] technical conditions [cf. [IUTchI], Remark 3.1.7, (i)]. Thus, a κ -coric rational function on $|C_{F_{\text{mod}}}|$ may also be regarded, by restriction, as a rational function on \underline{X}_K . Although the κ -coric rational functions do not form a monoid [i.e., the product of two κ -coric rational functions is not necessarily a κ -coric rational function], it nevertheless holds that $arbitrary\ positive\ powers$ of κ -coric rational functions are κ -coric. Moreover, every root of unity in F_{mod} is κ -coric; a rational function on $|C_{F_{\text{mod}}}|$ is κ -coric if and only if some positive power of the rational function is κ -coric. One verifies immediately that [despite the fact that the κ -coric rational functions do not form a monoid] these elementary properties that are satisfied by κ -coric rational functions are sufficient for conducting **Kummer theory** with κ -coric rational functions. Then [cf. [IUTchI], Example 5.1, (v), for more details]:

- The desired **decoupling** of the pseudo-monoid of κ -coric rational functions from the *unit group data* of (a^{Θ}) is achieved by means of the condition that **evaluation** at any of the **strictly critical points** an operation that may be performed at the level of **étale-like structures**, i.e., by **restricting Kummer classes** to decomposition groups of points yields a root of unity.
- The desired multiradial cyclotomic rigidity isomorphism is achieved by means of technique discussed in Example 2.13.1, (ii) i.e., involving

the elementary fact

$$\mathbb{Q}_{>0} \bigcap \widehat{\mathbb{Z}}^{\times} = \{1\}$$

— which is applied to the *pseudo-monoid of* κ -coric rational functions, i.e., as opposed to the entire multiplicative monoid K_X^{\times} .

As was mentioned in Example 2.13.1, (ii), this approach has the **disadvantage** of being **incompatible** with the **profinite topology** of the Galois or arithmetic fundamental groups involved [cf. the discussion of (iii) below; §3.6, (ii), below; [IUTchIII], Remark 2.3.3, (vii)]. Also, we remark that although this approach only allows one to reconstruct the desired cyclotomic rigidity isomorphism up to multiplication by ± 1 , this will not yield any problems since we are, in fact, only interested in reconstructing copies of the entire multiplicative monoid F_{mod}^{\times} , which is closed under inversion [cf. the discussion of [IUTchIII], Remark 2.3.3, (vi); [IUTchIII], Remark 3.11.4].

(iii) Naive approach to cyclotomic rigidity for theta functions: Fix $\underline{v} \in \underline{\mathbb{V}}^{\mathrm{bad}}$. Denote by means of a subscript \underline{v} the result of base-changing objects over K to $K_{\underline{v}}$. Thus, $X_{\underline{v}}$ is a "once-punctured Tate curve" over $K_{\underline{v}}$, hence determines a one-pointed stable curve of genus one $\mathfrak{X}_{\underline{v}}$ over the ring of integers $\mathcal{O}_{K_{\underline{v}}}$ of $K_{\underline{v}}$ [where, for simplicity, we omit the notation for the single marked point, which arises from the cusp of $X_{\underline{v}}$. In particular, the dual graph of the special fiber of $X_{\underline{v}}$ [i.e., more precisely: of $\mathfrak{X}_{\underline{v}}$] is a "loop" [i.e., more precisely, consists of a single vertex and a single edge, both ends of which abut to the single vertex]. In particular, the universal covering [in the sense of classical algebraic topology!] of this dual graph determines [what is called] a tempered covering $Y_{\underline{v}} \to X_{\underline{v}}$ [i.e., at the level of models over $\mathcal{O}_{K_{\underline{v}}}$, a tempered covering $\mathfrak{Y}_{\underline{v}} \to \mathfrak{X}_{\underline{v}}$ — cf. [André], §4; [Semi], Example 3.10], whose Galois group $\underline{\mathbb{Z}} \stackrel{\mathrm{def}}{=} \mathrm{Gal}(Y_{\underline{v}}/X_{\underline{v}})$ is noncanonically isomorphic to \mathbb{Z} . Thus,

the special fiber of $Y_{\underline{v}}$ [i.e., more precisely: of $\mathfrak{Y}_{\underline{v}}$] consists of an *infinite* chain of copies of the "once-punctured/one-pointed projective line", in which the "punctures/cusps" correspond to the points "1" of the copies of the projective line, and the point " ∞ " of each such copy is glued to the point "0" of the adjacent copy [cf. the upper portion of Fig. 3.9 below; the discussion at the beginning of [EtTh], §1; [IUTchII], Proposition 2.1; [IUTchII], Remark 2.1.1].

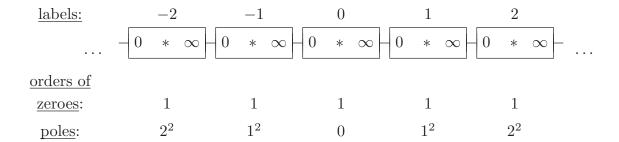

Fig. 3.9: Labels of irreducible components and orders of zeroes at cusps "*" and poles at irreducible components " \square " of the theta function $\ddot{\Theta}_{\underline{v}}$ on $\ddot{Y}_{\underline{v}}$

If one fixes one such copy of the once-punctured projective line, together with an isomorphism $\underline{\mathbb{Z}} \stackrel{\sim}{\to} \mathbb{Z}$, then the natural action of $\underline{\mathbb{Z}}$ on Y_v determines a natural bijection of the set of irreducible components of the special fiber of Y_v — or, alternatively, of the set of cusps of Y_v — with \mathbb{Z} [cf. the "labels" of Fig. 3.9]. The "multiplication by 2" endomorphism of the elliptic curve E_v [which may be thought of as the compactification of the affine hyperbolic curve $X_{\underline{v}}$] determines, via base-change by $Y_{\underline{v}} \to X_{\underline{v}}$, a double covering $\ddot{Y}_{\underline{v}} \to Y_{\underline{v}}$ [i.e., at the level of models over $\mathcal{O}_{K_{\underline{v}}}$, a double covering $\ddot{\mathfrak{Y}}_v \to \mathfrak{Y}_v$]. One verifies immediately that the set of irreducible components of the special fiber of $\ddot{Y}_{\underline{v}}$ [i.e., more precisely: of $\ddot{\mathfrak{Y}}_{\underline{v}}$] maps bijectively to the set of irreducible components of the special fiber of Y_v , while there exist precisely two cusps of $Y_{\underline{v}}$ over each cusp of $Y_{\underline{v}}$. The formal completion of $Y_{\underline{v}}$ along the smooth locus [i.e., the complement of "0" and "\infty"] of the irreducible component of the special fiber labeled 0 is naturally isomorphic [in a fashion compatible with a choice of isomorphism $\underline{\mathbb{Z}} \stackrel{\sim}{\to} \mathbb{Z}$ to a once-punctured copy of the multiplicative group "G_m". In particular, it makes sense to speak of the standard multiplicative coordinate " U_v " on this formal completion, as well as a square root [well-defined up to multiplication by ± 1] " \ddot{U}_v " of U_v on the base-change of this formal completion by $\ddot{Y}_{\underline{v}} \to Y_{\underline{v}}$. The **theta function**

$$\ddot{\Theta}_{\underline{v}} \ = \ \ddot{\Theta}_{\underline{v}}(\ddot{U}_{\underline{v}}) \ \stackrel{\mathrm{def}}{=} \ q_{\underline{v}}^{-\frac{1}{8}} \cdot \sum_{n \in \mathbb{Z}} \ (-1)^n \cdot q_{\underline{v}}^{\frac{1}{2}(n+\frac{1}{2})^2} \cdot \ddot{U}_{\underline{v}}^{2n+1}$$

may be thought of as a meromorphic function on $Y_{\underline{v}}$ [cf. [EtTh], Proposition 1.4, and the preceding discussion], whose zeroes are precisely the cusps, with multiplicity 1, and whose poles are supported on the special fiber of $Y_{\underline{v}}$, with multiplicity [relative to a square root $q_{\underline{v}}^{\frac{1}{2}}$ of $q_{\underline{v}}$] equal to j^2 at the irreducible component labeled j [cf. Fig. 3.9]. In fact, in inter-universal Teichmüller theory, we shall mainly be interested in [a certain constant multiple of] the reciprocal of an l-th root of this theta function, namely,

$$\underline{\underline{\Theta}}_{\underline{\underline{v}}} \stackrel{\text{def}}{=} \left\{ \left(\sqrt{-1} \cdot \sum_{m \in \mathbb{Z}} q_{\underline{v}}^{\frac{1}{2}(m + \frac{1}{2})^2} \right)^{-1} \cdot \left(\sum_{n \in \mathbb{Z}} (-1)^n \cdot q_{\underline{v}}^{\frac{1}{2}(n + \frac{1}{2})^2} \cdot U_{\underline{v}}^{n + \frac{1}{2}} \right) \right\}^{-\frac{1}{l}}$$

— which may be thought of as a meromorphic function on $\underline{\overset{}{\underline{Y}}}_{\underline{v}} \overset{\text{def}}{=} \overset{.}{Y}_{\underline{v}} \times_{\underline{X}_{\underline{v}}} \underline{\overset{\underline{X}}{=}}_{\underline{v}}$ that is normalized by the condition that it assumes a value $\in \mu_{2l}$ [i.e., a 2l-th root of unity] at the points of $\underline{\overset{.}{\underline{Y}}}_{\underline{v}}$ that lie over the torsion points of $E_{\underline{v}}$ of order precisely 4 and, moreover, meets the smooth locus of the irreducible component of the special fiber of $\underline{\overset{.}{\underline{Y}}}_{\underline{v}}$ [i.e., more precisely: of $\underline{\overset{.}{\underline{y}}}_{\underline{v}} \overset{\text{def}}{=} \overset{.}{\underline{y}}_{\underline{v}} \times_{\underline{x}_{\underline{v}}} \underline{\overset{.}{\underline{x}}_{\underline{v}}}$, where $\underline{\overset{.}{\underline{x}}}_{\underline{v}}$ and $\underline{\overset{.}{\underline{x}}}_{\underline{v}}$ denote the respective normalizations of $\underline{\overset{.}{\underline{x}}}_{\underline{v}}$ in $\underline{\overset{.}{\underline{X}}}_{\underline{v}}$ and $\underline{\overset{.}{\underline{x}}}_{\underline{v}}$] labeled 0 [i.e., the unique irreducible component of the special fiber of $\underline{\overset{.}{\underline{Y}}}_{\underline{v}}$ that maps to the irreducible component of the special fiber of $\underline{\overset{.}{\underline{Y}}}_{\underline{v}}$ labeled 0]. Such points of $\underline{\overset{.}{\underline{Y}}}_{\underline{v}}$ are referred to as **zero-labeled evaluation points** [cf., e.g., [IUTchII], Corollary 2.6]. At a very rough level,

the approach to multiradial decouplings/cyclotomic rigidity taken in the case of the Kummer theory of special functions that surrounds the formal monoid of (b^{Θ}) may be understood as being "roughly similar" to the approach discussed in (ii) in the case of the global realified Frobenioids of (c^{Θ}) , except that " κ -coric rational functions" are replaced by [normalized reciprocals of l-th roots of] **theta functions**.

[cf. the discussion of [IUTchII], Remark 1.1.1, (v); [IUTchIII], Remark 2.3.3]. That is to say,

- The desired **decoupling** [which is referred to in [EtTh], as "constant multiple rigidity"] of the [reciprocal of an l-th root of the] theta function from the unit group data of (a^{Θ}) is achieved by means of the condition that **evaluation** at any of the **zero-labeled evaluation points** an operation that may be performed at the level of **étale-like structures**, i.e., by **restricting Kummer classes** to decomposition groups of points yields a 2l-th root of unity.
- The desired multiradial cyclotomic rigidity isomorphism is, roughly speaking, achieved by means of the "mod N Kummer class version", for various positive integers N, of the technique discussed in Example 2.13.1, (ii) [cf., especially, the final display of Example 2.13.1, (ii)]: that is to say, such a "mod N version" is possible without any $\{\pm 1\}$ indeterminacies! precisely as a consequence of the fact that the order of each zero of $\ddot{\Theta}_{\underline{v}}$ at each cusp of $\ddot{Y}_{\underline{v}}$ is precisely one [cf., e.g., the discussion of [IUTchIII], Remark 2.3.3, (vi)].

In this context, we remark that the decomposition groups of zero-labeled evaluation points may be reconstructed by applying the theory of elliptic cuspidalizations developed in [AbsTopII], §3. This theory proceeds in an essentially parallel fashion to the theory of Belyi cuspidalizations [cf. the discussion of §3.3, (vi)]. That is to say, elliptic cuspidalizations are achieved as a formal consequence of the elementary observation that

the **dense open subscheme** of a once-punctured elliptic curve obtained by removing the N-torsion points, for N a positive integer, may be regarded — via the use of the "multiplication by N" endomorphism of the elliptic curve! — as a **finite étale covering** of the given once-punctured elliptic curve; in particular, the arithmetic fundamental group of such a dense open subscheme may be recovered from the arithmetic fundamental group of the given once-punctured elliptic curve by considering a suitable open subgroup of the latter arithmetic fundamental group [cf. [AbsTopII], Example 3.2; [AbsTopII], Corollaries 3.3, 3.4, for more details].

Another important observation in this context [cf. also §3.6, (ii), below; [IUTchIII], Remark 2.3.3, (vii)] is that the approach to cyclotomic rigidity described above involving "mod N Kummer classes" is manifestly compatible with the topology of the Galois or tempered arithmetic fundamental groups involved. Since this "mod N approach" depends, in an essential way, on the fact that the order of the zero of $\Theta_{\underline{v}}$ at each cusp of $Y_{\underline{v}}$ is precisely one [cf., the discussion of [IUTchIII], Remark 2.3.3, (vi)], it also serves to elucidate the importance of working with the first power of [reciprocals of l-th roots of the] theta function, i.e., as opposed to the M-th power, for $M \geq 2$ [cf. [IUTchII], Remark 3.6.4, (iii), (iv); [IUTchIII], Remark 2.3.3, (vii)]. On the other hand, the approach described thus far in the present (iii)

has one **fundamental deficiency**, namely, the fact that the *orders of the poles* of $\Theta_{\underline{v}}$ are **not compatible/symmetric** with respect to the action of $\underline{\mathbb{Z}}$ on $Y_{\underline{v}}$ [cf. Fig. 3.9] implies that

the approach described thus far in the present (iii) to multiradial cyclotomic rigidity — i.e., involving, in effect, the mod N Kummer classes of the [reciprocal of an l-th root of the] theta function — is not compatible with the \mathbb{Z} -symmetries of $Y_{\underline{v}}$ [cf. the discussion of [IUTchII], Remark 1.1.1, (v); [IUTchIII], Remark 2.3.3, (iv)].

Here, we note that the quotient $\underline{\mathbb{Z}} \xrightarrow{\sim} \mathbb{Z} \to \mathbb{Z}/l \cdot \mathbb{Z} = \mathbb{F}_l$ may be identified with the subgroup $\mathbb{F}_l \subseteq \mathbb{F}_l^{\times \pm}$ in the discussion of symmetries of $\Theta^{\pm \mathrm{ell}}NF$ -Hodge theaters in §3.3, (v). Also, we remark that the mod N Kummer class of the reciprocal of an l-th root of the theta function is **indeed compatible** with the $N \cdot l \cdot \mathbb{Z}$ -symmetries of $Y_{\underline{v}}$. This means that, as one varies N, the obstruction to finding a coherent system of basepoints — i.e., a coherent notion of the "zero label" — of the resulting projective system lies in

$$\mathbb{R}^1 \varprojlim_N \ N \cdot l \cdot \underline{\mathbb{Z}} \quad \stackrel{\sim}{\to} \quad \mathbb{R}^1 \varprojlim_N \ N \cdot l \cdot \mathbb{Z} \quad \stackrel{\sim}{\to} \quad l \cdot \widehat{\mathbb{Z}}/l \cdot \mathbb{Z} \quad \neq \quad 0$$

[cf. the discussion of [EtTh], Remark 2.16.1]. Put another way, one may only construct a coherent system of basepoints if one is willing to **replace** $\underline{\mathbb{Z}}$ by its profinite completion, i.e., to **sacrifice** the **discrete** nature of $\underline{\mathbb{Z}}$ ($\cong \mathbb{Z}$). It is for this reason that the property of compatibility with, say, the $l \cdot \underline{\mathbb{Z}}$ -symmetries of $Y_{\underline{v}}$ is referred to, in [EtTh], as **discrete rigidity**. This sort of discrete rigidity plays an important role in inter-universal Teichmüller theory since a failure of discrete rigidity would obligate one to work with $\widehat{\mathbb{Z}}$ -multiples/powers of divisors, line bundles, or meromorphic functions — a state of affairs that would, for instance, obligate one to sacrifice the crucial notion of **positivity/ampleness** in discussions of divisors and line bundles [cf. the discussion of [IUTchIII], Remark 2.1.1, (v)].

(iv) <u>Cyclotomic</u>, <u>discrete</u>, <u>and constant multiple rigidity for monotheta environments</u>: The *incompatibility* of the approach discussed in (iii) with <u>Z</u>-symmetries [cf. the discussion at the end of (iii)] is remedied in the theory of [EtTh] by working with **mono-theta environments**, as follows: Write $\mathfrak{L}_{\mathfrak{X}_{\underline{v}}}$ for the ample line bundle of degree 1 on $\mathfrak{X}_{\underline{v}}$ determined by the *unique marked point* of $\mathfrak{X}_{\underline{v}}$ and

for the various pull-backs, or restrictions, of $\mathfrak{L}_{\underline{x}_{\underline{v}}}$. Then the **theta function** $\Theta_{\underline{v}}$ on $Y_{\underline{v}}$ may be thought of as a **ratio** of *two sections* of the line bundle $\mathfrak{L}_{\underline{v}}$ over $\mathfrak{Y}_{\underline{v}}$, which may be described as follows:

· The **algebraic section** of $\ddot{\mathcal{L}}_{\underline{v}}$ is the section [well-defined up to a $K_{\underline{v}}^{\times}$ -multiple] whose zero locus coincides with the *locus of zeroes* of $\ddot{\Theta}_{\underline{v}}$. The pair consisting of the line bundle $\mathcal{L}_{\underline{v}}$ and this *algebraic section* admits $\underline{\mathbb{Z}}$ -symmetries [cf. Fig. 3.9], i.e., automorphisms that lie over the automorphisms of $\underline{\mathbb{Z}} = \operatorname{Gal}(Y_v/X_v)$.

· The **theta section** of $\ddot{\mathbb{Z}}_{\underline{v}}$ is the section [well-defined up to a $K_{\underline{v}}^{\times}$ -multiple] whose zero locus coincides with the *locus of poles* of $\ddot{\Theta}_{\underline{v}}$. One verifies immediately [cf. Fig. 3.9] that the *theta section* is **not compatible** with the \mathbb{Z} -symmetries of the *algebraic section*.

The analogous operation, for this line bundle-theoretic data, to considering various Kummer classes of the theta function is the operation of passing to the **tempered** arithmetic fundamental group of the \mathbb{G}_{m} -torsor $L_{\underline{\nu}}^{\times}$ associated to $L_{\underline{\nu}}$ or to the morphisms on tempered arithmetic fundamental groups induced by the algebraic and theta sections. Here, "mod N Kummer classes" correspond to considering the quotient of the tempered arithmetic fundamental group of $L_{\underline{\nu}}^{\times}$ that corresponds to coverings whose restriction to the " \mathbb{G}_{m} fibers" of the \mathbb{G}_{m} -torsor $L_{\underline{\nu}}^{\times}$ is dominated by the covering $\mathbb{G}_{\mathrm{m}} \to \mathbb{G}_{\mathrm{m}}$ given by raising to N-th power. Note that

neither the **ratio** of the *algebraic* and *theta sections* — i.e., the **theta** function! — **nor** the **pair** consisting of the *algebraic* and *theta sections* is **compatible** with the $\underline{\mathbb{Z}}$ -symmetries of Y_v .

On the other hand, it is not difficult to verify that the following triple of data is indeed **compatible**, **up to isomorphism**, with the $\underline{\mathbb{Z}}$ -symmetries of Y_v :

- $(a^{\mu-\Theta})$ the \mathbb{G}_{m} -torsor $L_{\underline{v}}^{\times}$;
- ($b^{\mu-\Theta}$) the group of automorphisms of $L_{\underline{v}}^{\times}$ generated by the $\underline{\mathbb{Z}}$ -symmetries of $L_{\underline{v}}^{\times}$ and the automorphisms determined by multiplication by a constant $\in K_{\underline{v}}^{\times}$;
- $(c^{\mu\text{-}\Theta}) \ \text{ the theta section of } \ddot{L}^{\times}_{\underline{v}} \ \stackrel{\text{def}}{=} \ L^{\times}_{\underline{v}}|_{\ddot{Y}_{v}}.$

Indeed, the asserted compatibility with the $\underline{\mathbb{Z}}$ -symmetries of $Y_{\underline{v}}$ is immediate for $(a^{\mu-\Theta})$ and $(b^{\mu-\Theta})$. On the other hand, with regard to $(c^{\mu-\Theta})$, a direct calculation shows that application of a $\underline{\mathbb{Z}}$ -symmetry has the effect of multiplying the theta section by some meromorphic function which is a product of integer powers of $U_{\underline{v}}$ and $q_{\underline{v}}^{\frac{1}{2}}$; moreover, a direct calculation shows that the group of automorphisms of $(b^{\mu-\Theta})$ is stabilized by conjugation by the operation of multiplying by such a meromorphic function. That is to say, by applying such multiplication operations, we conclude that the triple of data $(a^{\mu-\Theta})$, $(b^{\mu-\Theta})$, $(c^{\mu-\Theta})$ is indeed compatible, up to isomorphism, with the $\underline{\mathbb{Z}}$ -symmetries of $Y_{\underline{v}}$, as desired [cf. [EtTh], Proposition 2.14, (ii), (iii), for more details]. This argument motivates the following definition [cf. the discussion of [IUTchIII], Remark 2.3.4]:

The [mod N] mono-theta environment is defined by considering the [mod N] tempered arithmetic fundamental group versions of the "l-th roots" of the triple of data $(a^{\mu-\Theta})$, $(b^{\mu-\Theta})$, $(c^{\mu-\Theta})$ discussed above [cf. [EtTh], Definition 2.13, (ii)].

[Indeed, the data $(a^{\mu-\Theta})$, $(b^{\mu-\Theta})$, $(c^{\mu-\Theta})$ correspond, respectively, to the data of Definition 2.13, (ii), (a), (b), (c).] In particular, the **functoriality** of the tempered arithmetic fundamental group [essentially — cf. [EtTh], Proposition 2.14, (ii), (iii), for more details] implies that a **mono-theta environment** admits $l \cdot \mathbb{Z}$ -symmetries of the desired type, hence, in particular, that it satisfies the crucial property of **discrete rigidity** discussed in the final portion of (iii). Moreover, by forming suitable **commutators** in the group of automorphisms of $L_{\underline{v}}^{\times}$, one may

recover the desired **cyclotomic rigidity isomorphism** [cf. [EtTh], Corollary 2.19, (i); [IUTchII], Remark 1.1.1, for more details], i.e., that was discussed in a "rough form" in (iii), in a fashion that is

- **decoupled** from the unit group data of (a^{Θ}) ,
- · manifestly **compatible** with the **topology** of the tempered arithmetic fundamental groups involved [since one works with " $mod\ N$ " mono-theta environments!], and
- · **compatible** with the $\mathbb{F}_l^{\rtimes \pm}$ -symmetries of $\Theta^{\pm \text{ell}}$ NF-Hodge theaters [cf. §3.3, (v); [IUTchII], Remark 1.1.1, (iv), (v)].

Indeed, these multiradial decoupling/cyclotomic rigidity properties of monotheta environments are the main topic of [IUTchII], §1, and are summarized in [IUTchII], Corollaries 1.10, 1.12. Moreover, mono-theta environments have both étale-like and Frobenius-like versions, i.e., they may be constructed naturally [cf. [IUTchII], Proposition 1.2, (i), (ii)] either

- · from the **tempered arithmetic fundamental group** [regarded as an abstract topological group!] of \underline{X}_{v} , or
- · from a certain "tempered Frobenioid", i.e., a model Frobenioid [cf. §3.3, (iii)] obtained by considering suitable divisors, line bundles, and meromorphic functions on the various tempered coverings of $\underline{\underline{X}}_{v}$.

Finally, we close with the important *observation* that the various **rigidity** properties of mono-theta environments discussed above may be regarded as

essentially formal consequences of the quadratic structure of the commutators of the theta groups — or, equivalently, of the curvature, or first Chern class — associated to the line bundle L_{X_v}

[cf. the discussion of [IUTchII], Remark 1.1.1, (iv), (v); [IUTchIII], Remark 2.1.1]. This observation is of interest in that it shows that the theory of [EtTh] [or, indeed, a substantial portion of inter-universal Teichmüller theory!] yields an interesting alternative interpretation for the structure of theta groups to the classical representation-theoretic interpretation, i.e., involving irreducible representations of theta groups [cf. [IUTchIII], Remark 2.3.4, (iv)].

(v) Various approaches to cyclotomic rigidity: The discussion in the present §3.4 of various properties of the three approaches to cyclotomic rigidity that appear in inter-universal Teichmüller theory is summarized in Fig. 3.10 below. The most naive approach, involving well-known properties from local class field theory applied to the data " $G_k \sim \mathcal{O}_k^{\triangleright}$ ", is compatible with the profinite topology of the Galois or arithmetic fundamental groups involved, but suffers from the fundamental defect of being uniradial, i.e., of being "un-decouplable" from the unit group data of (a^{Θ}) [cf. the discussion of (i)]. By contrast, the approaches discussed in (ii) and (iv) involving κ -coric rational functions and mono-theta environments satisfy the crucial requirement of multiradiality, i.e., of being "decouplable" from the unit group data of (a^{Θ}) . The approach via mono-theta environments also satisfies the important property of being compatible with the topology of the tempered arithmetic fundamental groups involved. By contrast, the approach via κ -coric rational functions is not compatible with the profinite

topology of the Galois or arithmetic fundamental groups involved. This incompatibility in the case of the Kummer theory surrounding the **global** data of (c^{Θ}) will not, however, pose a problem, since compatibility with the topologies of the various Galois or [possibly tempered] arithmetic fundamental groups involved will only be of interest in the case of the Kummer theory surrounding the **local** data of (a^{Θ}) and (b^{Θ}) [cf. §3.6, (ii), below; [IUTchIII], Remark 2.3.3, (vii), (viii)].

Fig. 3.10: Three approaches to cyclotomic rigidity

§3.5. Remarks on the use of Frobenioids: The theory of Frobenioids was developed in [FrdI], [FrdII] as a

solution to the problem of providing a unified, intrinsic category-theoretic characterization of various types of categories of line bundles and divisors that frequently appeared in the author's research on the arithmetic of hyperbolic curves and, moreover, seemed, at least from a heuristic point of view, to be remarkably similar in structure.

These papers [FrdI], [FrdII] on Frobenioids were written in the spring of 2005, when the author only had a relatively rough, sketchy idea of how to formulate inter-universal Teichmüller theory. In particular,

anyone who reads these papers [FrdI], [FrdII] — or indeed, the Frobenioid-theoretic portion of [EtTh] — under the expectation that they were written as an optimally efficient presentation of precisely those portions of the theory of Frobenioids that are actually used in inter-universal Teichmüller theory will undoubtedly be disappointed.

In light of this state of affairs, it seems appropriate to pause at this point to make a few remarks on the use of Frobenioids in inter-universal Teichmüller theory. First of all,

• at $\underline{v} \in \underline{\mathbb{V}}^{\mathrm{arc}}$, the ["archimedean"] Frobenioids that appear in interuniversal Teichmüller theory [cf. [IUTchI], Example 3.4] are essentially equivalent to the **topological monoid** $\mathcal{O}_{\mathbb{C}}^{\triangleright}$ [i.e., the multiplicative topological monoid of nonzero complex numbers of norm ≤ 1] and hence may be ignored.

On the other hand,

at $\underline{v} \in \underline{\mathbb{V}}^{\text{non}}$, all of the ["nonarchimedean"] Frobenioids that appear in inter-universal Teichmüller theory [cf., e.g., [IUTchI], Fig. I1.2] — except for the *tempered Frobenioids* mentioned in §3.4, (iv)! — are essentially equivalent to *either* the data [consisting of an abstract indtopological monoid equipped with a continuous action by an abstract topological group]

"
$$G_k \curvearrowright \mathcal{O}_{\overline{k}}^{\triangleright}$$
"

of Example 2.12.1, (i), or the data [consisting of an abstract ind-topological monoid equipped with a continuous action by an abstract topological group]

"
$$\Pi_X \curvearrowright \mathcal{O}_{\overline{k}}^{\triangleright}$$
"

of Example 2.12.3, (ii) [where Π_X is possibly replaced by the tempered arithmetic fundamental group of X], or the data obtained from one of these two types of data by replacing " $\mathcal{O}_{\overline{k}}^{\triangleright}$ " by some subquotient of " $\mathcal{O}_{\overline{k}}^{\triangleright}$ " [as in Example 2.12.2, (i), (ii)].

Moreover, all of these "nonarchimedean" Frobenioids are **model Frobenioids** [cf. the discussion of §3.3, (iii)]. The *only other types of Frobenioids* — all of which are **model Frobenioids** [cf. the discussion of §3.3, (iii)] — that appear in interuniversal Teichmüller theory are

- the [possibly realified] global Frobenioids associated to NF's [cf. the discussion of §3.4, (ii)], which admit a *simple elementary description* as categories of *arithmetic line bundles* on NF's [cf. [FrdI], Example 6.3; [IUTchIII], Example 3.6; [Fsk], §2.10, (i), (ii)];
- the **tempered Frobenioids** mentioned in §3.4, (iv).

Here, we note that

these last two examples — i.e., global Frobenioids and tempered Frobenioids — differ fundamentally from the previous examples, which were essentially equivalent to an ind-topological monoid that was, in some cases, equipped with a continuous action by a topological group, in that their **Picard groups** [cf. [FrdI], Theorem 5.1] admit **non-torsion elements**.

Indeed, global Frobenioids contain objects corresponding to arithmetic line bundles whose arithmetic degree is $\neq 0$, while tempered Frobenioids contain objects corresponding to line bundles for which arbitrary positive tensor powers are nontrivial such as [strictly speaking, the pull-back to $\underline{\underline{Y}}_{\underline{v}}$ of] the line bundle " $L_{\underline{v}}$ " of §3.4, (iv). Finally, we remark that although the theory of tempered Frobenioids, which is developed in [EtTh], §3, §4, §5, is somewhat complicated, the only portions of these tempered Frobenioids that are actually used in inter-universal Teichmüller theory are the portions discussed in §3.4, (iii), (iv), i.e.,

- (a^{t-F}) the "theta monoids" generated by local units [i.e., " \mathcal{O}^{\times} "] and nonnegative powers of roots of the [reciprocals of l-th roots of] theta functions that are constructed from tempered Frobenioids [cf. [IUTchI], Example 3.2; [IUTchII], Example 3.2, (i)];
- $(b^{\text{t-F}})$ the **mono-theta environments** constructed from tempered Frobenioids [cf. [IUTchII], Proposition 1.2, (ii)], which are related to the monoids of $(a^{\text{t-F}})$, in that they share the same submonoids of roots of unity.

Indeed, étale-like versions of this "essential Frobenius-like data" of $(a^{\text{t-F}})$ and $(b^{\text{t-F}})$ are discussed in [IUTchII], Corollaries 1.10, 1.12; [IUTchIII], Theorem 2.2, (ii) [cf. the data " $(a_{\underline{v}})$, $(b_{\underline{v}})$, $(c_{\underline{v}})$, $(d_{\underline{v}})$ " of loc. cit.]. Thus, from the point of view of studying inter-universal Teichmüller theory,

one may essentially *omit* the detailed study of [EtTh], §3, §4, §5, either by accepting the construction of the data (a^{t-F}) and (b^{t-F}) "on faith" or by regarding this data as data constructed from the scheme-theoretic objects discussed in [EtTh], §1, §2.

§3.6. Galois evaluation, labels, symmetries, and log-shells: In the present §3.6, we discuss the theory of Galois evaluation of the κ -coric rational functions and theta functions of §3.4, (ii), (iii). Here, we remark that the term "Galois evaluation" refers to the passage

abstract functions \mapsto values

by first passing from Frobenius-like — that is to say, in essence, [pseudomonoid-theoretic — versions of these functions [cf. the discussion of §3.4, (ii), (iii); §3.5] to étale-like versions of these functions via various forms of Kummer theory as discussed in §3.4, (ii), (iii), then evaluating these étale-like functions by restricting them to decomposition subgroups [that, say, arise from closed points of the curve under consideration of the [possibly tempered] arithmetic fundamental group under consideration to obtain étale-like versions of the values of interest, and finally applying the **Kummer theory** of the constant base field [i.e., as discussed in Example 2.12.1 to obtain **Frobenius-like** versions of the values of interest [cf. Fig. 3.11 below; [IUTchII], Remark 1.12.4]. In fact, it is essentially a **tautology** that the *only way* to construct an assignment "abstract functions \mapsto values" that is **compatible** with the operation of forming **Kummer classes** is precisely by applying [some variant of] this technique of Galois evaluation [cf. the discussion of [IUTchII], Remark 1.12.4]. Moreover, it is interesting in this context to observe [cf. the discussion of [IUTchII], Remark 1.12.4] that the well-known Section Conjecture of anabelian geometry — which, at least historically, was expected to be related to diophantine geometry [cf. the discussion of [IUTchI], §15] — suggests strongly that, when one applies the technique of Galois evaluation, in fact,

the **only suitable subgroups** of the [possibly tempered] arithmetic fundamental group under consideration for the operation of "evaluation" are precisely the **decomposition subgroups** that arise from the closed points of the curve under consideration!

From this point of view, it is also of interest to observe that, in the context of the evaluation of theta functions at torsion points [cf. (ii) below], it will be necessary

to apply a certain "combinatorial version of the Section Conjecture" [cf. [IUTchI], Remark 2.5.1; the proof of [IUTchII], Corollary 2.4, (i)]. Finally, we remark that, in order to give a precise description of the Galois evaluation operations that are performed in inter-universal Teichmüller theory, it will be necessary to consider, in substantial detail,

- the labels of the points at which the functions are to be evaluated [i.e., the points that give rise to the decomposition subgroups mentioned above],
- the symmetries that act on these labels [cf. §3.3, (v)], and
- · the log-shells that serve as containers for the values that are constructed.

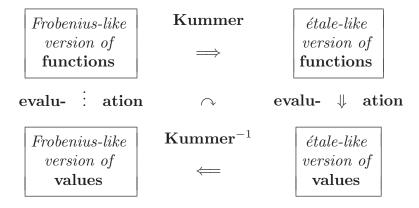

Fig. 3.11: The technique of Galois evaluation

(i) Passage to the étale-picture, combinatorial uni-/multiradiality of Recall from the discussion of §3.3, (vi), that the \mathcal{D} - $\Theta^{\pm \text{ell}}$ NF-Hodge symmetries: theaters associated to the $\Theta^{\pm \text{ell}}$ NF-Hodge theaters " \bullet " in the log-theta-lattice are vertically coric. That is to say, one may think of a \mathcal{D} - $\Theta^{\pm \text{ell}}NF$ -Hodge theater, considered up to an indeterminate isomorphism, as an invariant of each vertical line of the log-theta-lattice. Moreover, the étale-like portion [i.e., the " G_v 's"] of the data of (a^{Θ}) , or, equivalently, (a^q) , of §3.3, (vii), again considered up to an indeterminate isomorphism, may be thought of as an object constructed from the \mathcal{D} - $\Theta^{\pm \text{ell}}NF$ -Hodge theater associated to the $\Theta^{\pm \text{ell}}NF$ -Hodge theater " \bullet " under consideration. In particular,

if one takes the radial data to consist of the \mathcal{D} - $\Theta^{\pm \text{ell}}NF$ -Hodge theater associated to some vertical line of the log-theta-lattice [considered up to an indeterminate isomorphism!, the coric data to consist of the étalelike portion [again considered up to an indeterminate isomorphism!] of the data of (a^{Θ}) , or, equivalently, (a^q) , of §3.3, (vii), and the radial algorithm to be the assignment [i.e., "construction"] of the above discussion, then one obtains a radial environment, shown in Fig. 3.12 below, that is ["tautologically"!] multiradial [cf. [IUTchII], Corollary 4.11; [IUTchII], Fig. 4.3].

Indeed, this multiradial environment may be thought of as being simply a slightly more complicated version of the multiradial environment of Example 3.2.2, (ii). The diagram obtained by including, in the diagram of Fig. 3.12, not just two collections of radial data [that arise, say, from two adjacent vertical lines of the log-theta-lattice, but rather the collections of radial data that arise from all of the vertical lines of the log-theta-lattice is referred to as the **étale-picture** [cf. [IUTchII], Fig. 4.3]. Despite its tautological nature,

the multiradiality — i.e., permutability of \mathcal{D} - $\Theta^{\pm \text{ell}}$ NF-Hodge theaters associated to distinct vertical lines of the log-theta-lattice — of the étale-picture is nonetheless somewhat remarkable since [prior to passage to the étale-picture!] the log-theta-lattice does not admit symmetries that permute distinct vertical lines of the log-theta-lattice.

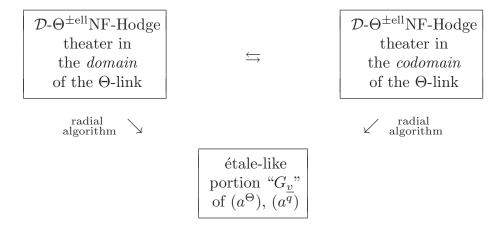

Fig. 3.12: The multiradiality of \mathcal{D} - $\Theta^{\pm \text{ell}}$ NF-Hodge theaters

Next, we consider the respective $\mathbb{F}_l^{\rtimes\pm}$ - and \mathbb{F}_l^* -symmetries of the consituent \mathcal{D} - $\Theta^{\pm \mathrm{ell}}$ NF-Hodge theaters [cf. §3.3, (v)]. In this context, it is useful to introduce symbols " \succ " and " \gt ":

- ">" denotes the **entire set** \mathbb{F}_l that appears in the discussion of Fig. 3.8 in §3.3, (v), i.e., the notation "[...]" in the *upper left-hand corner* of Fig. 3.8 [cf. [IUTchI], Fig. 6.5].
- ">" denotes the **entire set** \mathbb{F}_l^* that appears in the discussion of Fig. 3.8 in §3.3, (v), i.e., the notation "[...]" in the *upper right-hand corner* of Fig. 3.8 [cf. [IUTchI], Fig. 6.5].
- · The **gluing** shown in Fig. 3.8 may be thought of as an *assignment* that sends

$$0, \succ \mapsto >$$

[cf. [IUTchI], Proposition 6.7; [IUTchI], Fig. 6.5; the discussion of [IUTchII], Remark 3.8.2, (ii); the symbol " \triangle " of [IUTchII], Corollary 4.10, (i)].

Ultimately, we shall be interested in computing weighted averages of log-volumes at the various labels in \mathbb{F}_l or \mathbb{F}_l^* ($\subseteq |\mathbb{F}_l| \stackrel{\text{def}}{=} \mathbb{F}_l^* \cup \{0\}$) [cf. [IUTchI], Remark 5.4.2; the computations of [IUTchIV], §1]. From this point of view, it is natural to think in terms of formal sums with rational coefficients

$$[0], \quad [|j|] \stackrel{\text{def}}{=} \frac{1}{2}([j] + [-j]),$$
$$[\succ] \stackrel{\text{def}}{=} \frac{1}{l}([0] + [1] + [-1] + \dots + [l^*] + [-l^*]),$$
$$[\gt] \stackrel{\text{def}}{=} \frac{1}{l^*}([|1|] + \dots + [|l^*|]) = \frac{1}{2l^*}([1] + [-1] + \dots + [l^*] + [-l^*])$$

— where the "j" and "…" indicate arguments that range within the positive integers between 1 and $l^* = \frac{1}{2}(l-1)$. Note that these assignments

of formal sums are *compatible* with the *gluing* "0, $\succ \mapsto >$ ", i.e., relative to which

$$[0] \mapsto [>], [>] \mapsto [>], \frac{1}{(l^*+1)}([0] + [\ |1|\] + \ldots + [\ |l^*|\]) \mapsto [>]$$

— where we note that such relations may be easily verified by observing that the coefficients of "[j]" and "[-j]" always coincide and are independent of j; thus, these relations may be verified by substituting a single indeterminate "w" for all of the symbols "[0]", "[j]", and "[-j]".

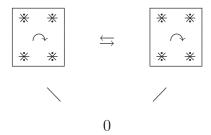

Fig. 3.13: Combinatorial multiradiality of \mathbb{F}_{l}^{*} -symmetries

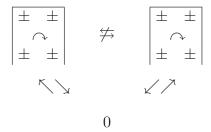

Fig. 3.14: Combinatorial uniradiality of $\mathbb{F}_{l}^{\times\pm}$ -symmetries

If one extracts from the étale-picture the various \mathbb{F}_l^* -symmetries of the respective \mathcal{D} - $\Theta^{\pm \mathrm{ell}}$ NF-Hodge theaters, then one obtains a diagram as in Fig. 3.13 above, i.e., a diagram of various distinct, independent \mathbb{F}_l^* -actions that are "glued together at a common symbol 0" [cf. the discussion of [IUTchII], Remark 4.7.4; [IUTchII], Fig. 4.2]. This diagram may be thought of as a sort of combinatorial prototype for the phenomenon of multiradiality. On the other hand, if one extracts from the étale-picture the various $\mathbb{F}_l^{\times \pm}$ -symmetries of the respective \mathcal{D} - $\Theta^{\pm \mathrm{ell}}$ NF-Hodge theaters, then one obtains a diagram as in Fig. 3.14 above, i.e., a diagram of various mutually interfering $\mathbb{F}_l^{\times \pm}$ -actions that interfere with one another as a consequence of the fact that they are "glued together at a common symbol 0" [cf. the discussion of [IUTchII], Remark 4.7.4; [IUTchII], Fig. 4.1]. This diagram may be thought of as a sort of combinatorial prototype for the phenomenon of uniradiality. Finally, in this context, it is also of interest to observe that, if, in accordance with the point of view of the discussion of §2.14,

one thinks of \mathbb{F}_l as a sort of **finite discrete approximation** of "Z" [cf. [IUTchI], Remark 6.12.3, (i); [IUTchII], Remark 4.7.3, (i)],

and one thinks "Z" as the **value group** of the various completions [say, for simplicity, at $\underline{v} \in \underline{\mathbb{V}}^{\text{non}}$] of K, then

the \mathbb{F}_l^* -symmetry corresponds to a symmetry that only involves the non-unit portions of these value groups at various $\underline{v} \in \underline{\mathbb{V}}^{\text{non}}$, while the $\mathbb{F}_l^{\times \pm}$ -symmetry is a symmetry that involves a sort of "juggling" between local unit groups and local value groups.

This point of view is consistent with the fact [cf. (iii) below; Example 2.12.3, (v); §3.3, (ii), (vii); §3.4, (ii)] that the \mathbb{F}_l^* -symmetry is related *only* to the Kummer theory surrounding the **global value group data** (c^{Θ}) , while [cf. (ii) below; Example 2.12.3, (v); §3.3, (ii), (vii); §3.4, (iii), (iv)] the $\mathbb{F}_l^{\times \pm}$ -symmetry is related to both the [local] unit group data (a^{Θ}) and the local value group data (b^{Θ}) , which are "juggled" about by the log-links of the log-theta-lattice.

(ii) Theta values and local diagonals via the $\mathbb{F}_l^{\rtimes \pm}$ -symmetry: Let $\underline{v} \in \underline{\mathbb{V}}^{\text{bad}}$. Write

$$\Pi_{\underline{v}} \subseteq \Pi_{v}^{\pm} \subseteq \Pi_{v}^{\text{cor}}$$

[cf. [IUTchII], Definition 2.3, (i)] for the inclusions of tempered arithmetic fundamental groups [for suitable choices of basepoints] determined by the finite étale coverings $\underline{X}_{\underline{v}} \to \underline{X}_{\underline{v}} \to C_{\underline{v}}$ [cf. the notational conventions discussed at the beginning of §3.4, (iii)]. These tempered arithmetic fundamental groups of hyperbolic orbicurves over $K_{\underline{v}}$ admit natural outer surjections to $G_{\underline{v}}$; write $\Delta_{\underline{v}} \subseteq \Delta_{\underline{v}}^{\pm} \subseteq \Delta_{\underline{v}}^{\text{cor}}$ for the respective kernels of these surjections. In fact, $\Pi_{\underline{v}}^{\pm}$ and $\Pi_{\underline{v}}^{\text{cor}}$, together with the above inclusions, may be reconstructed functorially from the topological group $\Pi_{\underline{v}}$ [cf. [EtTh], Proposition 2.4]. The $\mathbb{F}_l^{\times\pm}$ -symmetries of a $\Theta^{\pm \text{ell}}$ NF-Hodge theater [cf. §3.3, (v)] induce outer automorphisms of $\Pi_{\underline{v}}^{\pm}$. Indeed, these outer automorphisms may be thought of as the outer automorphisms of $\Pi_{\underline{v}}^{\pm}$ induced by conjugation in $\Pi_{\underline{v}}^{\text{cor}}$ by the quotient group $\Pi_{\underline{v}}^{\text{cor}}/\Pi_{\underline{v}}^{\pm}$, which admits a natural outer isomorphism $\mathbb{F}_l^{\times\pm} \xrightarrow{\sim} \Pi_{\underline{v}}^{\text{cor}}/\Pi_{\underline{v}}^{\pm}$ [cf. [IUTchII], Corollary 2.4, (iii)]. Moreover, since these outer automorphisms of $\Pi_{\underline{v}}^{\pm}$ arise from K-linear automorphisms of the hyperbolic curve \underline{X}_K [cf. the discussion of §3.3, (v)], let us observe that

the outer automorphisms of $\Pi_{\underline{v}}^{\pm}$ under consideration may, in fact, be thought of as $\Delta_{\underline{v}}^{\pm}$ -outer automorphisms of $\Pi_{\underline{v}}^{\pm}$ [i.e., automorphisms defined up to composition with an inner automorphism induced by conjugation by an element of $\Delta_{\underline{v}}^{\pm}$].

Next, let us recall from the discussion of §3.3, (v), concerning the $\mathbb{F}_l^{\times\pm}$ -symmetry that elements of \mathbb{F}_l may be thought of — up to $\mathbb{F}_l^{\times\pm}$ -indeterminacies that may in fact, as a consequence of the *structure* of a $\Theta^{\pm\mathrm{ell}}NF$ -Hodge theater, be synchronized in a fashion that is independent of the choice of $\underline{v} \in \underline{\mathbb{V}}^{\mathrm{bad}}$ [cf. [IUTchI], Remark 6.12.4, (i), (ii), (iii)] — as labels of cusps of $\underline{X}_{\underline{v}}$. Moreover, such cusps of $\underline{X}_{\underline{v}}$ may be thought of, by applying a suitable functorial group-theoretic algorithm, as certain conjugacy classes of subgroups [i.e., cuspidal inertia subgroups] of $\Pi_{\underline{v}}^{\pm}$ [cf. [IUTchI], Definition 6.1, (iii)]. In particular, the above observation implies that, if we think of $G_{\underline{v}}$ as a quotient of one of the tempered arithmetic fundamental groups $\Pi_{\underline{v}}$, $\Pi_{\underline{v}}^{\mathrm{cor}}$ discussed above, and we consider copies of this quotient $G_{\underline{v}}$ equipped with labels

— where we think of $t \in \mathbb{F}_l$ as a conjugacy class of cuspidal inertia subgroups of Π_v^{\pm} — then

the action of the $\mathbb{F}_l^{\times \pm}$ -symmetry [i.e., by conjugation in $\Pi_{\underline{v}}^{\text{cor}}$] on these labeled quotients $\{(G_{\underline{v}})_t\}_{t\in\mathbb{F}_l}$ induces **symmetrizing isomorphisms** between these labeled quotients that are **free** of any **inner automorphism indeterminacies** [cf. [IUTchII], Corollary 3.5, (i); [IUTchII], Remark 3.5.2, (iii); [IUTchII], Remark 4.5.3, (i)].

The existence of these symmetrizing isomorphisms is a phenomenon that is sometimes referred to as **conjugate synchronization**. Note that this sort of situation differs radically from the situation that arises for the isomorphisms induced by conjugation in $G_K \stackrel{\text{def}}{=} \operatorname{Gal}(\overline{F}/K)$ between the various decomposition groups of \underline{v} [that is to say, copies of " $G_{\underline{v}}$ "], i.e., isomorphisms which are only well-defined up to composition with some **indeterminate inner automorphism** of the decomposition group under consideration [cf. the discussion of [IUTchII], Remark 2.5.2, (iii)]. In this context, since tempered arithmetic fundamental groups, unlike conventional profinite étale fundamental groups, are only defined at a specific $\underline{v} \in \underline{\mathbb{V}}^{\text{bad}}$, one technical issue that arises, when one considers the task of relating the symmetrizing isomorphisms discussed above at different $\underline{v} \in \underline{\mathbb{V}}^{\text{bad}}$ [or, indeed, to the theory at valuations $\underline{\in} \underline{\mathbb{V}}^{\text{good}}$] is

the issue of *comparing* **tempered** *and* **profinite** *conjugacy classes* of various types of subgroups [i.e., such as cuspidal inertia groups] — an issue that is resolved [cf. the application of [IUTchI], Corollary 2.5, in the proof of [IUTchII], Corollary 2.4] by applying the theory of [Semi].

The symmetrizing isomorphisms discussed above may be applied not only to copies of the étale-like object $G_{\underline{v}}$ but also to various Frobenius-like objects that are "closely related" to $G_{\underline{v}}$ [cf. the pairs " $G_k \curvearrowright \mathcal{O}_{\overline{k}}^{\triangleright}$ " of Example 2.12.1; [IUTchII], Corollary 3.6, (i)]. Moreover, an analogous theory of symmetrizing isomorphisms may be developed at valuations $\in \underline{\mathbb{V}}^{\text{good}}$ [cf. [IUTchII], Corollary 4.5, (iii); [IUTchII], Corollary 4.6, (iii)]. The **graphs**, or **diagonals**, of these symmetrizing isomorphisms at various valuations $\in \underline{\mathbb{V}}$ may be thought of as corresponding to the **symbol** " \succ " discussed in (i), or indeed, after applying the **gluing** that appears in the structure of a $\Theta^{\pm \text{ell}}$ NF-Hodge theater [cf. (i); §3.3, (v)], to the **symbols** "0", " \gt " [cf. [IUTchII], Corollary 3.5, (iii); [IUTchII], Corollary 3.6, (iii); [IUTchII], Corollary 4.5, (iii); [IUTchII], Corollary 4.6, (iii); [IUTchII], Corollary 4.10, (i)]. Moreover,

the data labeled by these symbols " \succ ", "0", ">", form the data that is ultimately actually used in the **horizontally coric unit group portion** (a^{Θ}) , (a^q) [cf. §3.3, (vii)] of the data in the codomain and domain of the Θ -link [cf. [IUTchIII], Theorem 1.5, (iii)].

The significance of this approach to constructing the data of (a^{Θ}) , (a^q) lies in the fact that the "descent" [cf. [IUTchIII], Remark 1.5.1, (i)] from the individual labels $t \in \mathbb{F}_l$ to the symbols " \succ "/"0"/" \gt " that is effected by the various symmetrizing isomorphisms gives rise to horizontally coric data — i.e., data that is shared by the codomain and domain of the Θ -link — that serves as a container [cf. the discussion of (iv) below] for the various theta values [well-defined up to

multiplication by a 2l-th root of unity

$$\underline{q}^{j^2}$$

— where we think of $j=1,\ldots,l^*$ as corresponding to an element of \mathbb{F}_l^* obtained by identifying two elements $\pm t \in \mathbb{F}_l^\times \subseteq \mathbb{F}_l$ — obtained by **Galois evaluation** [cf. [IUTchII], Corollary 2.5; [IUTchII], Remark 2.5.1; [IUTchII], Corollary 3.5, (ii); [IUTchII], Corollary 3.6, (ii)], i.e., by restricting the **Kummer classes** of the [reciprocals of l-th roots of] **theta functions** on $\underline{\underline{\mathring{Y}}}_{\underline{v}}$ discussed in §3.4, (iii) [cf. also the data " (a^{t-F}) " discussed in §3.5]

· first to the **decomposition groups**, denoted by the notation " $\Drive{\triangleright}$ ", in the open subgroup of $\Pi_{\underline{v}}$ corresponding to $\underline{\underline{Y}}_{\underline{v}}$ determined [up to conjugation in $\Pi_{\underline{v}}$ — cf. [IUTchII], Proposition 2.2; [IUTchII], Corollary 2.4] by the **connected** — i.e., so as not to give rise to distinct basepoints for distinct labels $j=1,\ldots,l^*$ [cf. the discussion of [IUTchII], Remarks 2.6.1, 2.6.2, 2.6.3] — "line **segment**" of labels of irreducible components of the special fiber of $Y_{\underline{v}}$

$$\{-l^*, -l^* + 1, \dots, -1, 0, 1, \dots, l^* - 1, l^*\} \subseteq \mathbb{Z}$$

[cf. Fig. 3.9 and the surrounding discussion; [IUTchII], Remark 2.1.1, (ii)]; and

· then to the **decomposition groups** associated to "evaluation points" — i.e., cusps translated by a zero-labeled evaluation point — labeled by $\pm t \in \mathbb{F}_l^{\times} \subseteq \mathbb{F}_l$.

Finally, we remark that the **Kummer theory** that relates the corresponding étale-like and Frobenius-like data that appears in the various symmetrizing isomorphisms just discussed only involves local data, i.e., the data of (a^{Θ}) and (b^{Θ}) , hence [cf. the discussion of §3.4, (v); Fig. 3.10] is compatible with the topologies of the various tempered or profinite Galois or arithmetic fundamental groups involved. The significance of this compatibility with topologies lies in the fact it means that the Kummer isomorphisms that appear may be computed relative to some finite étale covering of the schemes involved, i.e., relative to a situation in which — unlike the situation that arises if one considers some sort of projective limit of multiplicative monoids associated to rings — the ring structure of the schemes involved is still intact. That is to say, since the log-link is defined by applying the formal power series of the natural logarithm, an object that can only be defined if both the additive and the multiplicative structures of the [topological] rings involved are available,

this **computability** allows one to **compare** — hence to establish the **compatibility** of — the various **symmetrizing isomorphisms** just discussed in the *codomain* and *domain* of the **log-link** [cf. [IUTchII], Remark 3.6.4, (i); [IUTchIII], Remark 1.3.2; the discussion of Step (vi) of the proof of [IUTchIII], Corollary 3.12].

This *compatibility* plays an important role in inter-universal Teichmüller theory.

- (iii) Number field values and global diagonals via the \mathbb{F}_l^* -symmetry: We begin by considering certain field extensions of the field F_{mod} : write
 - $F_{\text{sol}} \subseteq \overline{F}$ for the maximal solvable extension of F_{mod} in \overline{F} [cf. [IUTchI], Definition 3.1, (b)];
 - $F(\mu_l, C_F)$ for the field obtained by adjoining to the function field of C_F the l-th roots of unity [cf. the field " $F(\mu_l) \cdot L_C$ " of [IUTchI], Remark
 - $F(\mu_l, \kappa$ -sol) for the field obtained by adjoining to $F(\mu_l, C_F)$ arbitrary roots of F_{sol} -multiples of κ -coric rational functions [cf. §3.4, (ii)] in $F(\mu_l, C_F)$ [cf. the field " $F(\mu_l) \cdot L_C(\kappa\text{-sol})$ " of [IUTchI], Remark 3.1.7, (iii)];
 - $F(\underline{C}_K)$ for the Galois closure over the field $F(\mu_l, C_F)$ of the function field of \underline{C}_K [cf. the field " $L_C(\underline{C}_K)$ " of [IUTchI], Remark 3.1.7, (iii)].

Then one verifies immediately, by applying the fact that the finite group $SL_2(\mathbb{F}_l)$ [where we recall from §3.3, (i), that $l \geq 5$] is perfect, that

 $F(\mu_l, \kappa\text{-sol})$ and $F(\underline{C}_K)$ are linearly disjoint over $F(\mu_l, C_F)$ [cf. [IUTchI], Remark 3.1.7, (iii)].

It then follows, in an essentially formal way, from this linear disjointness [cf. [IUTchI], Remark 3.1.7, (ii), (iii); [IUTchI], Example 5.1, (i), (v); [IUTchI], Remark 5.1.5; [IUTchII], Corollary 4.7, (i), (ii); [IUTchII], Corollary 4.8, (i), (ii)] that:

· the various **elements** in

$$F_{\rm mod}$$
 or $F_{\rm sol}$

may be obtained by Galois evaluation, i.e., by restricting the Kummer classes of the κ -coric rational functions discussed in §3.4, (ii), to the various decomposition groups that arise, respectively, from F_{mod} - or $F_{\rm sol}$ -rational points;

- · this construction of F_{mod} or F_{sol} via Galois evaluation may be done in a fashion that is **compatible** with the labels $\in \mathbb{F}_l^*$ and the \mathbb{F}_l^* -symmetry that appear in a $\Theta^{\pm \text{ell}}$ NF-Hodge theater [cf. the discussion of §3.3, (v); the right-hand side of Fig. 3.8];
- · in particular, this compatibility with labels and the \mathbb{F}_{l}^{*} -symmetry induces symmetrizing isomorphisms between copies of F_{mod} or F_{sol} that determine graphs, or diagonals, which may be thought of as corresponding to the **symbol** ">" [cf. the discussion of (i), (ii)].

In this context, we note that this approach to constructing elements of NF's by restricting Kummer classes of rational functions on hyperbolic curves to decomposition groups of points defined over an NF is precisely the approach taken in the functorial algorithms of [AbsTopIII], Theorem 1.9 [cf., especially, [AbsTopIII], Theorem 1.9, (d)]. Also, we observe that, although much of the above discussion runs in a somewhat parallel fashion to the discussion in (ii) of the $\mathbb{F}_l^{\times \pm}$ -symmetry and the construction of theta values via Galois evaluation, there are important differences, as well, between the theta and NF cases [cf. [IUTchIII], Remark [2.3.3]:

· First of all, the symmetrizing isomorphisms/diagonals associated to the \mathbb{F}_{l}^{*} -symmetry are **not** compatible with the symmetrizing isomorphisms/diagonals associated to the $\mathbb{F}_l^{\times\pm}$ -symmetry, except on the respective restrictions of these two collections of symmetrizing isomorphisms to **copies of** F_{mod} [cf. [IUTchII], Remark 4.7.2].

- Unlike the *Kummer theory* applied in the *theta case*, the **Kummer theory** applied in the *NF case* is **not** compatible with the **topologies** of the various profinite Galois or arithmetic fundamental groups that appear [cf. the discussion of §3.4, (v)]. On the other hand, this will not cause any problems since there is **no issue**, in the *NF case*, of applying formal power series such as the power series of the *natural logarithm* [cf. the final portion of the discussion of (ii); [IUTchIII], Remark 2.3.3, (vii), (viii)].
- · In the Galois evaluation applied in the theta case, one is concerned with constructing, at a level where the **arithmetic holomorphic structure** [i.e., the ring structure] is **still intact**, theta values that depend, in an essential way, on the label "j". By contrast, in the Galois evaluation applied in the NF case, one only constructs, at such a level where the arithmetic holomorphic structure is still intact, the totality of [various copies of] the multiplicative monoid F_{mod}^{\times} associated to the number field F_{mod} : that is to say, a **dependence** on the label "j" only appears at the level of the **mono-analytic structures** constituted by the **global realified Frobenioids** of (c^{Θ}) , i.e., in the form of a sort of ratio, or weight, "j2" [cf. the fourth display of [IUTchII], Corollary 4.5, (v)] between the arithmetic degrees at the label "j" and the arithmetic degrees at the label "1" [cf. [IUTchIII], Remark 2.3.3, (iii); [IUTchIII], Remark 3.11.4, (i)].

In the context of this final difference between the theta and NF cases, it is perhaps of interest to observe that a similar sort of "weighted copy" $(F_{\text{mod}}^{\times})^{j^2}$ ($\subseteq F_{\text{mod}}^{\times}$) of F_{mod}^{\times} is **not possible** at the level of **arithmetic holomorphic structures** [that is to say, in the sense that it is not compatible with the additive interpretation of line bundles, i.e., in terms of modules] since this "weighted copy" $(F_{\text{mod}}^{\times})^{j^2}$ ($\subseteq F_{\text{mod}}^{\times}$) is **not closed under addition** [cf. the discussion of the final portion of §3.3, (iv); [AbsTopIII], Remark 5.10.2, (iv)].

- (iv) <u>Actions on log-shells</u>: At this point, the reader may have noticed *two* apparent shortcomings [which are, in fact, closely related!] in the theory of Galois evaluation developed thus far in the present §3.6:
 - · Unlike the case with the Kummer theory of κ -coric rational functions and theta functions/mono-theta environments discussed in §3.4, the discussion of Galois evaluation given above does not mention any **multiradiality** properties.
 - · Ultimately, one is interested in relating [the Kummer theory surrounding] Frobenius-like structures such as the theta values and copies of NF's that arise from Galois evaluation in the domain of the Θ -link to [the Kummer theory surrounding] Frobenius-like structures in the codomain of the Θ -link, i.e., in accordance with the discussion of the technique of mono-anabelian transport in §2.7, §2.9. On the other hand, since the theta values and copies of NF's that arise from Galois evaluation are not [necessarily] local units at the various $\underline{v} \in \underline{\mathbb{V}}$, it is by no means clear how to relate this Galois evaluation output data to the codomain of the Θ -link

using the horizontally coric portion — i.e., the [local] unit group **portion** (a^{Θ}) and (a^q) — of the Θ -link.

In fact, these two shortcomings are closed related: That is to say, the existence of the obstruction discussed in §3.4, (i), to the approach to Kummer theory taken in Example 2.12.1, (ii), that arises from the natural action " $\mathcal{O}_{\overline{k}}^{\times \mu} \curvearrowleft \widehat{\mathbb{Z}}^{\times}$ " implies — in light of the nontrivial extension structure that exists between the value groups and units of finite subextensions of "k" in " \overline{k} " [cf. the discussion in the final portion of Example 2.12.1, (iii) — that, at least in any sort of a priori or natural sense,

the output data — i.e., theta values and copies of NF's — of the Galois evaluation operations discussed in (ii), (iii) above [i.e., which lies in various copies of "k"! is by no means multiradial [cf. [IUTchII], Remark 2.9.1, (iii); [IUTchII], Remark 3.4.1, (ii); [IUTchII], Remark 3.7.1; [IUTchIII], Remark 2.2.1, (iv)].

One of the fundamental ideas of inter-universal Teichmüller theory is that

one may apply the theory of the log-link and log-shells to obtain a solution to these closely related shortcomings.

More precisely, from the point of view of the log-theta-lattice, the log-link from the lattice point (n, m-1) to the lattice point (n, m) [where $n, m \in \mathbb{Z}$] allows one to construct [cf. the notation of Example 2.12.3, (iv)] a holomorphic Frobeniuslike log-shell "I" at (n,m) from the " $\mathcal{O}_{\overline{k}}^{\times \boldsymbol{\mu}}$ " at (n,m-1). Thus,

the output data — i.e., theta values and copies of NF's — of the Galois evaluation operations discussed in (ii), (iii) above at (n, m) acts **naturally** on the " $\mathcal{I} \otimes \mathbb{Q}$ " [i.e., the copy of "k"] at (n, m) that arises from this log-link from (n, m-1) to (n, m) [cf. [IUTchIII], Proposition 3.3, (i); [IUTchIII], Proposition 3.4, (ii); [IUTchIII], Definition 3.8, (ii)].

On the other hand, this gives rise to a fundamental dilemma:

Since the construction of the log-link — i.e., at a more concrete level, the formal power series of the natural logarithm — can only be defined if both the additive and the multiplicative structures of the [topological] rings involved are available, the log-link and hence, in particular, the construction of log-shells just discussed, at, say, the lattice point (n, m), are **meaningless**, at least in any a priori sense, from the point of view of the lattice point (n+1,m), i.e., the *codomain* of the Θ -link from (n,m) to (n+1,m) [cf. [IUTchIII], Remark 3.11.3; Steps (iii) and (iv) of the proof of [IUTchIII], Corollary 3.12].

Another of the fundamental ideas of inter-universal Teichmüller theory is the following [cf. the discussion in §3.3, (ii), of the symmetry of the [infinite!] vertical lines of the log-theta-lattice with respect to arbitrary vertical translations!

By considering structures that are invariant with respect to vertical shifts of the log-theta-lattice — i.e., vertically coric structures such as holomorphic/mono-analytic étale-like log-shells that serve as containers for Frobenius-like objects such as holomorphic Frobenius-like

log-shells [cf. Fig. 3.15 below] or notions of vertical invariance such as **upper semi-commutativity** or **log-volume compatibility** [cf. Example 2.12.3, (iv)] — and then transporting these invariant structures to the opposite side of the Θ -link by means of **mono-analytic Frobenius-like** log-shells [i.e., which may be constructed directly from the data " $\mathcal{O}_{\overline{k}}^{\times \mu}$ " that appears in the horizontally coric data (a^{Θ}) , (a^q) of the Θ -link], one may construct **multiradial containers** for the output data — i.e., **theta values** and **copies of NF's** — of the Galois evaluation operations discussed above.

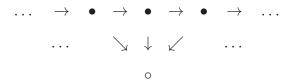

Fig. 3.15: A vertical line of the log-theta-lattice [shown horizontally]: holomorphic Frobenius-like structures "•" at each lattice point related, via various Kummer isomorphisms [i.e., vertical or diagonal arrows], to vertically coric holomorphic étale-like structures "o"

Here, we observe that each of the *four* types of log-shells discussed in Example 2.12.3, (iv), plays an *indispensable role* in the theory [cf. [IUTchIII], Remark 3.12.2, (iv), (v)]:

- the holomorphic Frobenius-like log-shells satisfy the property [unlike their mono-analytic counterparts!] that the log-link whose construction requires the use of the topological ring structure on these log-shells! may be applied to them, as well as the property [unlike their étale-like counterparts!] that they belong to a fixed vertical position of a vertical line of the log-theta-lattice, hence are meaningful even in the absence of the log-link;
- the holomorphic étale-like log-shells allow one [unlike their Frobenius-like counterparts!] to relate holomorphic Frobenius-like log-shells at different vertical positions of a vertical line of the log-theta-lattice to one another in a fashion [unlike their mono-analytic counterparts!] that takes into account the log-link [whose construction requires the use of the topological ring structure on these log-shells!];
- the mono-analytic Frobenius-like log-shells satisfy the property [unlike their holomorphic counterparts!] that they may be constructed directly from the data " $\mathcal{O}_{\overline{k}}^{\times \mu}$ " that appears in the horizontally coric data (a^{Θ}) , (a^q) of the Θ -link, as well as the property [unlike their étale-like counterparts!] that they belong to a fixed vertical position of a vertical line of the log-theta-lattice, hence are meaningful even in the absence of the log-link;
- the mono-analytic étale-like log-shells satisfy the property [unlike their holomorphic counterparts!] that they may be constructed directly from the data " G_k " that appears in the horizontally coric data (a^{Θ}) , (a^q) of the Θ -link, as well as the property [unlike their Frobenius-like counterparts, when taken alone!] that they may be used, in conjunction with their Frobenius-like counterparts, to relate mono-analytic Kummer theory

[i.e., Kummer isomorphisms between mono-analytic Frobenius-like/étale-like log-shells] to *holomorphic Kummer theory* [i.e., Kummer isomorphisms between holomorphic Frobenius-like/étale-like log-shells].

(v) <u>Processions</u>: In order to achieve the multiradiality discussed in (iv) for Galois evaluation output data, one further technique must be introduced, namely, the use of processions [cf. [IUTchI], Definition 4.10], which serve as a sort of mono-analytic substitute for the various labels in \mathbb{F}_l^* , $|\mathbb{F}_l|$ (= $\mathbb{F}_l^* \cup \{0\}$), or \mathbb{F}_l discussed in (i). That is to say, since these labels are closely related to the various cuspidal inertia subgroups of the geometric fundamental groups " Δ " of the hyperbolic orbicurves involved [cf. the discussion of (i), (ii); §2.13; §3.3, (v)], it follows that these labels are not horizontally coric [i.e., not directly visible to the opposite side of the Θ -link — cf. the discussion of [IUTchIV], Remark 3.6.3, (ii)] and indeed do not even admit, at least in any a priori sense, any natural multiradial formulation. The approach taken in inter-universal Teichmüller theory to dealing with this state of affairs is to consider the diagram of inclusions of finite sets

$$\mathbb{S}_1^{\pm} \quad \hookrightarrow \quad \mathbb{S}_{1+1=2}^{\pm} \quad \hookrightarrow \quad \dots \quad \hookrightarrow \quad \mathbb{S}_{j+1}^{\pm} \quad \hookrightarrow \quad \dots \quad \hookrightarrow \quad \mathbb{S}_{1+l^*=l^\pm}^{\pm}$$

— where we write $\mathbb{S}_{j+1}^{\pm} \stackrel{\text{def}}{=} \{0,1,\ldots,j\}$, for $j=0,\ldots,l^*$, and we think of each of these finite sets as being subject to arbitrary permutation automorphisms. That is to say, we think of

the set \mathbb{S}_{j+1}^{\pm} as a **container** for the labels $0, 1, \ldots, j$, and of the **label** "j" as "**some**" element of this container set, i.e., for each j, there is an *indeterminacy of* j+1 *possibilities* for the element of this container set that corresponds to j.

Here, we note in passing that this sort of indeterminacy is substantially milder than the indeterminacies that occur if one considers each j only as "some" element of $\mathbb{S}_{l^{\pm}}$, in which case every j is subject to an indeterminacy of l^{\pm} possibilities — cf. [IUTchI], Proposition 6.9, (i), (ii). One then regards

each such *container set* as an **index set** for a collection — which is referred to as a "**capsule**" [cf. [IUTchI], §0] — of copies of some sort of **étale-like** mono-analytic prime-strip.

An étale-like mono-analytic prime-strip is, roughly speaking, a collection of copies of data " G_k " indexed by $\underline{v} \in \underline{\mathbb{V}}$ [cf. [IUTchI], Fig. I1.2, and the surrounding discussion; [IUTchI], Definition 4.1, (iii)]. Now each étale-like mono-analytic prime-strip, in a capsule, as described above, gives rise, at each $v \in \mathbb{V}$, to

mono-analytic étale-like log-shells, on which the Galois evaluation output data acts, in the fashion described in (iv), up to various indeterminacies that arise from the passage from holomorphic Frobenius-like log-shells to mono-analytic étale-like log-shells [cf. Figs. 3.16, 3.17 below, where each "/ $^{\pm}$ " denotes an étale-like mono-analytic prime-strip].

These *indeterminacies* will be discussed in more detail in §3.7, (i), below. In fact, ultimately, from the point of various **log-volume** computations, it is more natural

to consider the *Galois evaluation output data* as acting, up to various indeterminacies, on certain **tensor products** of the various log-shells indexed by a particular container set \mathbb{S}_{j+1}^{\pm} . Such tensor products are referred to as **tensor packets** [cf. [IUTchIII], Propositions 3.1, 3.2].

$$\underline{\underline{q}}^1 \curvearrowright \qquad \underline{\underline{q}}^{j^2} \curvearrowright \qquad \underline{\underline{q}}^{(l^*)^2} \curvearrowright$$

$$/^{\pm} \hookrightarrow /^{\pm}/^{\pm} \hookrightarrow \ldots \hookrightarrow /^{\pm}/^{\pm} \ldots /^{\pm} \hookrightarrow \ldots \hookrightarrow /^{\pm}/^{\pm} \ldots ... /^{\pm}$$

$$\mathbb{S}_1^{\pm} \qquad \mathbb{S}_{1+1=2}^{\pm} \qquad \mathbb{S}_{j+1}^{\pm} \qquad \mathbb{S}_{1+l^*=l^{\pm}}^{\pm}$$

Fig. 3.16: Theta values acting on tensor packets

$$(F_{\mathrm{mod}}^{\times})_{1} \curvearrowright \qquad (F_{\mathrm{mod}}^{\times})_{j} \curvearrowright \qquad (F_{\mathrm{mod}}^{\times})_{l^{*}} \curvearrowright$$

$$/^{\pm} \hookrightarrow /^{\pm}/^{\pm} \hookrightarrow \ldots \hookrightarrow /^{\pm}/^{\pm} \ldots /^{\pm} \hookrightarrow \ldots \hookrightarrow /^{\pm}/^{\pm} \ldots /^{\pm}$$

$$\mathbb{S}_{1}^{\pm} \qquad \mathbb{S}_{1+1=2}^{\pm} \qquad \mathbb{S}_{j+1}^{\pm} \qquad \mathbb{S}_{1+l^{*}=l^{\pm}}^{\pm}$$

Fig. 3.17: Copies of F_{mod}^{\times} acting on tensor packets

- §3.7. <u>Log-volume estimates via the multiradial representation</u>: In the following, we outline the **statements** of and **relationships** between the **main results** [cf. [IUTchIII], Theorem 3.11; [IUTchIII], Corollary 3.12; [IUTchIV], Theorem 1.10; [IUTchIV], Corollaries 2.2, 2.3] of inter-universal Teichmüller theory.
- (i) <u>Multiradial representation of the Θ-pilot object up to mild indeterminacies</u>: The content of the discussion of §3.4, §3.5, and §3.6 may be summarized as follows [cf. [IUTchIII], Theorem A; [IUTchIII], Theorem 3.11]:

the data in the domain (a^{Θ}) , (b^{Θ}) , and (c^{Θ}) [cf. §3.3, (vii)] of the Θ -link may be expressed in a fashion that is **multiradial**, when considered up to certain **indeterminacies** (Ind1), (Ind2), (Ind3) [cf. the discussion below], with respect to the radial algorithm

$$(a^\Theta),\,(b^\Theta),\,(c^\Theta)\quad \mapsto \quad (a^\Theta)$$

[cf. the discussion at the beginning of §3.4] by regarding this [**Frobenius-like!**] data (a^{Θ}) , (b^{Θ}) , and (c^{Θ}) [up to the indeterminacies (Ind1), (Ind2), (Ind3)] as data [cf. Fig. 3.18 below] that is **constructed** by

- · first applying the Kummer theory and multiradial decouplings/cyclotomic rigidity of κ -coric rational functions in the case of (c^{Θ}) [cf. §3.4, (ii), (v)] and of theta functions/monotheta environments in the case of (b^{Θ}) [cf. §3.4, (iii), (iv), (v)]; §3.5; and
- then applying the theory of Galois evaluation and symmetrizing isomorphisms at l-torsion points, together with the $\mathbb{F}_l^{\times\pm}$ -symmetry in the case of (b^{Θ}) [cf. §3.6, (i), (ii), (iv), (v)] and at decomposition groups corresponding to F_{mod} - $/F_{\text{sol}}$ -rational points, together with the \mathbb{F}_l^* -symmetry in the case of (c^{Θ}) [cf. §3.6, (i), (iii), (iv), (v)].

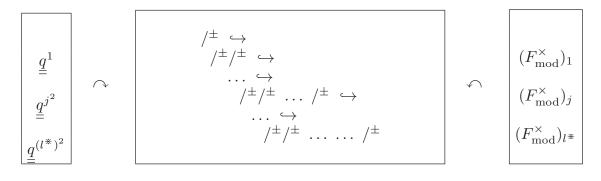

Fig. 3.18: The full multiradial representation

Here, we recall from §3.6, (iv), (v), that the data (b^{Θ}) and (c^{Θ}) act on **processions** of **tensor packets** that arise from the **mono-analytic étale-like log-shells** constructed from the data (a^{Θ}) . The *indeterminacies* (Ind1),(Ind2), (Ind3) referred to above act on these *log-shells* and may be described as follows:

- (Ind1) These indeterminacies are the **étale-transport** indeterminacies [cf. §2.7, (vi); Example 2.12.3, (i)] that occur as a result of the *automorphisms* [which, as was discussed in Example 2.12.3, (i), do *not*, in general, preserve the *ring structure!*] of the various " G_k 's" that appear in the data (a^{Θ}) .
- (Ind2) These indeterminacies are the **Kummer-detachment** indeterminacies [cf. §2.7, (vi)] that occur as a result of the *identification* of, or *confusion* between, *mono-analytic Frobenius-like* and *mono-analytic étale-like log-shells* [cf. the discussion of §3.6, (iv)]. At a more concrete level, these indeterminacies arise from the action of the group of "isometries" which is often denoted

"
$$Ism(-)$$
"

- [cf. [IUTchII], Example 1.8, (iv)] of the data " $\mathcal{O}_{\overline{k}}^{\times \mu}$ " [which we regard as equipped with a system of integral structures, or lattices] of (a^{Θ}) , i.e., the **compact** topological group of G_k -equivariant automorphisms of the ind-topological module $\mathcal{O}_{\overline{k}}^{\times \mu}$ that, for each open subgroup $H \subseteq G_k$, preserve the lattice $\mathcal{O}_{\overline{k}}^{\times \mu} \subseteq (\mathcal{O}_{\overline{k}}^{\times \mu})^H$.
- (Ind3) These indeterminacies are the **Kummer-detachment** indeterminacies [cf. §2.7, (vi)] that occur as a result of the **upper semi-commutativity** [cf. Example 2.12.3, (iv); §3.6, (iv)] of the log-**Kummer correspondence** [cf. [IUTchIII], Remark 3.12.2, (iv), (v)], i.e., the system of log-links and **Kummer isomorphisms** of a particular vertical line of the log-theta-lattice [cf. Fig. 3.15].

In addition to these "explicitly visible" indeterminacies, there are also "invisible indeterminacies" [cf. [IUTchIII], Remark 3.11.4] that in fact arise, but may be ignored in the above description, essentially as a formal consequence of the way in which the various objects that appear are defined:

The various **theta values** and **copies of** F_{mod}^{\times} that occur as *Frobenius-like Galois evaluation output data* at various *vertical positions* of the log-Kummer correspondence [cf. the discussion of §3.6, (iv), (v)] **satisfy** an important "**non-interference**" property [cf. [IUTchIII], Proposition 3.5, (ii), (c); [IUTchIII], Proposition 3.10, (ii)]: namely, the *intersection* of such output data with the product of the local units [i.e., " \mathcal{O}^{\times} "] at those elements of $\underline{\mathbb{V}}$ at which the output data in question occurs consists only of **roots of unity**. As a result, the only "possible confusion", or "indeterminacy", that occurs as a consequence of possibly applying iterates of the log-link to the various local units consists of a possible multiplication by a root of unity. On the other hand, since the theta values and copies of F_{mod}^{\times} that occur as Frobenius-like Galois evaluation output data are **defined** in such a way as to be **stable** under the action by multiplication by such roots of unity, this indeterminacy may, in fact, be ignored [cf. the discussion of [IUTchIII], Remark 3.11.4, (i)].

The indeterminacy of possible multiplication by ± 1 in the cyclotomic rigidity isomorphism that is applied in the Kummer theory of κ -coric rational functions [cf. the final portion of the discussion of §3.4, (ii)] may be ignored since the global Frobenioids related to the data (c^{Θ}) , i.e., that arise from copies of F_{mod} , only require the use of the totality of [copies of] the multiplicative monoid F_{mod}^{\times} , which is stabilized by the operation of inversion [cf. the discussion of [IUTchIII], Remark 3.11.4, (i)].

At this point, it is useful to recall [cf. the discussion at the beginning of §3.4, (i)] that it was possible to define, in §3.3, (vii), the **gluing isomorphisms** that constitute the Θ -link between the domain data (a^{Θ}) , (b^{Θ}) , (c^{Θ}) and the codomain data (a^q) , (b^q) , (c^q) precisely because we worked with various abstract monoids or global realified Frobenioids, i.e., as opposed to the "conventional scheme-like representations" of this data (a^{Θ}) , (b^{Θ}) , (c^{Θ}) in terms of theta values and copies of NF's. In particular, one way to interpret the multiradial representation discussed above [cf. the discussion of "simultaneous execution" at the beginning of §2.9 and §3.4, (i)] is as follows:

This **multiradial representation** may be understood as the [somewhat surprising!] assertion that not only the domain data (a^{Θ}) , (b^{Θ}) , (c^{Θ}) , but also the codomain data (a^q) , (b^q) , (c^q) — or, indeed,

any collection of data

[i.e., not just the *codomain* data (a^q) , (b^q) , (c^q) !] that is isomorphic to the *domain* data (a^{Θ}) , (b^{Θ}) , (c^{Θ})

[cf., e.g., the discussion concerning " $\frac{q}{2}$ " in the second to last display of §3.8, below] — can, when regarded up to suitable **indeterminacies**, be represented via the "**conventional scheme-like representation**" of (a^{Θ}) , (b^{Θ}) , (c^{Θ}) in a fashion that is **compatible** with the **original** "conventional scheme-like representation" of the given collection of data [i.e., such as the "conventional scheme-like representation" of the data (a^q) , (b^q) , (c^q)].

If we specialize this *interpretation* to the case of the data (a^q) , (b^q) , (c^q) , then we obtain the following [again *somewhat surprising!*] *interpretation* of the *multiradial representation* discussed above [cf. the discussion of §2.4]:

If one takes a **symmetrized average** over $N = 1^2, 2^2, \dots, j^2, \dots, (l^*)^2$, and one works up to suitable **indeterminacies**, then

the **arithmetic line bundle** determined by " $\underline{\underline{q}}$ "

[i.e., the 2*l*-th roots of the *q*-parameter at the valuations $\in \underline{\mathbb{V}}^{\text{bad}}$, or, alternatively, the "q-pilot object" may be identified — i.e., from the point of view of performing any sort of computation that takes into account the "suitable indeterminacies" — with

the arithmetic line bundle determined by " q^N "

[i.e., the "Θ-pilot object"] obtained by raising the arithmetic line bundle determined by " \underline{q} " to the N-th tensor power

[cf. Fig. 3.19 below, where "LHS" and "RHS" denote, respectively, the left-hand and right-hand sides, i.e., the domain and codomain, of the Θ -link].

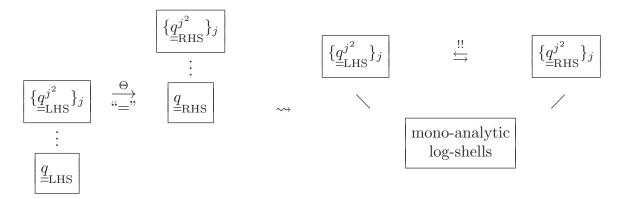

Fig. 3.19: The gluing, or tautological identification "=", of the Θ -link from the point of view of the multiradial representation

- (ii) Log-volume estimates: The interpretation discussed in the final portion of (i) leads naturally to an estimate of the arithmetic degree of the q-pilot object [cf. [IUTchIII], Theorem B; [IUTchIII], Corollary 3.12], as follows [cf. Steps (x), (xi) of the proof of [IUTchIII], Corollary 3.12; [IUTchIII], Fig. 3.8]:
- (1^{est}) One starts with the *Frobenius-like* version of the q-pilot object i.e., " q_{RHS} " — on the RHS of the Θ -link. All subsequent computations are to be understood as computations that are performed relative to the fixed arithmetic holomorphic structure of this RHS of the Θ -link.
- (2^{est}) The isomorphism class determined by this q-pilot object in the global **realified Frobenioid** of (c^q) [cf. §3.3, (vii)] is sent, via the Θ -link, to the isomorphism class determined by the Θ -pilot object — i.e., " $\{q^{j^2}\}_j$ " — in the global realified Frobenioid of (c^{Θ}) [cf. §3.3, (vii)].
- (3est) One then applies the multiradial representation discussed in (i) [cf. Fig. 3.19].
- (4est) One observes that the log-volume, suitably normalized, on the log-shells that occur in this multiradial representation is **invariant** with respect to the indeterminacies (Ind1) and (Ind2), as well as with respect to the invisible indeterminacies, discussed in (i).
- (5^{est}) On the other hand, the **upper semi-commutativity** indeterminacy (Ind3) — i.e., "commutativity" at the level of inclusions of regions in logshells [cf. the discussion of Example 2.12.3, (iv)] — may be understood as asserting that the log-volume of the multiradial representation of the Θ -pilot object must be interpreted as an **upper bound**.

- (6est) The **multiradial representation** of the Θ -pilot object " $\{q_j^{j^2}\}_j$ " can only be **compared** to the **isomorphism class** determined by the original q-pilot object " q_j " in the global realified Frobenioid of (c^q) , i.e., not to the specific arithmetic line bundle given by a copy of the trivial arithmetic line bundle with fixed local trivializations "1" multiplied by 2l-th roots of q-parameters [cf. [IUTchIII], Remark 3.12.2, (v)].
- (7est) In particular, in order to perform such a **comparison** between the **multiradial representation** of the Θ -pilot object " $\{q_{\pm \text{LHS}}^{j^2}\}_j$ " and the **isomorphism class** determined by the original q-pilot object " $q_{\pm \text{RHS}}$ " in the global realified Frobenioid of (c^q) , it is necessary to make the output data of the multiradial representation into a collection of " \mathcal{O}_k -modules" [where we use the notation " \mathcal{O}_k " to denote the various completions of the ring of integers of K at, for simplicity, the valuations $\in \mathbb{V}^{\text{non}}$], i.e., relative to the **arithmetic holomorphic structure** of the **RHS** of the Θ -link!
- (8^{est}) Such " \mathcal{O}_k -modules" are obtained by, essentially [cf. [IUTchIII], Remark 3.9.5, for more details], forming the " \mathcal{O}_k -modules generated by" the various tensor packets of log-shells [cf. the discussion of §3.6, (iv), (v)] that appear in the multiradial representation, i.e., which, a priori, are [up to a factor given by a suitable power of "p"] just topological modules

"
$$\log(\mathcal{O}_k^{\times}) \otimes \log(\mathcal{O}_k^{\times}) \otimes \ldots \otimes \log(\mathcal{O}_k^{\times})$$
"

- that is to say, tensor products of j+1 copies of " $\log(\mathcal{O}_k^{\times})$ " at the portion of the multiradial representation labeled by j. This operation yields a "slightly enlarged multiradial representation", which is referred to as the **holomorphic hull** [cf. [IUTchIII], Corollary 3.12; [IUTchIII], Remark 3.9.5] of the multiradial representation.
- (9est) The log-volume, when applied to the original q-pilot object "q " or to the Θ -pilot object " $\{q_j^{j^2}\}_j$ ", may be interpreted as the **arithmetic** degree of these objects [cf. §2.2; [IUTchIII], Remark 1.5.2, (i), (iii); [IUTchIII], Proposition 3.9, (iii); [IUTchIII], Remark 3.10.1, (iv)].
- (10^{est}) In particular, any **upper bound** on the *log-volume* of the *holomorphic hull* of the *multiradial representation* of the Θ -**pilot object** " $\{q^{j^2}\}_j$ " may be **interpreted** [cf. [IUTchIII], Remark 3.12.2, (i), (ii)] as an upper bound on the log-volume of the *original [Frobenius-like] q-pilot object* "q ".
- (11^{est}) This comparison of log-volumes was obtained by considering the *images* of various *Frobenius-like* objects in the *étale-like* tensor packets of log-shells of the multiradial representation. In particular, one must apply the \log -Kummer correspondence on *both* the LHS [in the case of the Θ -pilot object " $\{q_{LHS}^{j^2}\}_j$ "] and the RHS [in the case of the original [Frobenius-like] q-pilot object " q_{LHS} "] of the Θ -link. On the other hand, this does not affect the resulting inequality, in light of the compatibility of log-volumes with the arrows of the \log -Kummer correspondence [cf. Example 2.12.3, (iv); §3.6, (iv); [IUTchIII], Remark 3.12.2, (iv), (v)].
- (12^{est}) Thus, in summary, one obtains an **inequality** of **log-volumes** [cf. [IUTchIII],

Theorem B; [IUTchIII], Corollary 3.12]

$$\log\text{-vol.}\left(\begin{array}{c} \Theta\text{-pilot object up to}\\ \mathbf{mild indeterminacies},\\ \text{i.e., (Ind1), (Ind2), (Ind3),}\\ \text{plus formation of}\\ \mathbf{holomorphic\ hull} \end{array}\right) \quad \geq \quad \log\text{-vol.}\left(\mathbf{\textit{q-pilot object}}\right) \quad (\approx 0)$$

- where the log-volume of the q-pilot object on the right-hand side of the inequality is negative and of negligible absolute value by comparison to the terms of interest [to be discussed in more detail in (iv) below] on the left-hand side of the inequality.
- (iii) Comparison with a result of Stewart-Yu: Recall that in [StYu], an inequality is obtained which may be thought of as a sort of "weak version of the ABC Conjecture", i.e., which is, roughly speaking, weaker than the inequality of the usual ABC Conjecture in that it contains an undesired exponential operation " $\exp(-)$ " in its upper bound. This sort of deviation from the inequality of the usual ABC Conjecture is of interest from the point of view of the "vertical shift" discussed in §3.6, (iv), which, on the one hand, gives rise to the **indeterminacy** (Ind3) [cf. the discussion of (i); (ii), (5^{est})] and, on the other hand, arises from the fact that the **horizontally coric** portion of the data related by the Θ -link differs from the sort of data in which one is ultimately interested precisely by a single iterate of the log-link, i.e., a single vertical shift in the log-theta-lattice.
- (iv) Computation of log-volumes: Let us return to the discussion of (ii). It remains to compute the *left-hand side* of the *inequality* of (ii), (12^{est}), in more elementary terms. This is done in [IUTchIV], Theorem 1.10. This computation yields a rather strong version of the Szpiro Conjecture inequality, in the case of elliptic curves over NF's that admit initial Θ -data [cf. §3.3, (i)] that satisfies certain technical conditions. The existence of such initial Θ -data that satisfies certain technical conditions is then verified in [IUTchIV], Corollary 2.2, (ii), for elliptic curves over NF's that satisfy certain technical conditions by applying the techniques of [GenEll], §3, §4. Here, we remark in passing that the **prime number** l that appears in this initial Θ -data constructed in [IUTchIV], Corollary 2.2, (ii), is roughly of the order of the square root of the height of the elliptic curve under consideration [cf. [IUTchIV], Corollary 2.2, (ii), (C1)]. This initial Θ-data yields a version of the Szpiro Conjecture inequality [cf. [IUTchIV], Corollary 2.2, (ii), (iii), which, although somewhat weaker and less effective than the inequality of [IUTchIV], Theorem 1.10, is still rather strong in the sense that it implies that, if we restrict, for simplicity, to the case of *elliptic curves over* \mathbb{Q} , then

the " ϵ terms" that appear in the Szpiro Conjecture inequality concerning the **height** h may be **bounded above** by terms of the order of

$$h^{1/2} \cdot \log(h)$$

— i.e., at least in the case of elliptic curves over $\mathbb Q$ whose **moduli** are "compactly bounded", in the sense that the moduli lie inside given fixed compact subsets of the sets of rational points of the moduli of elliptic curves over \mathbb{R} and \mathbb{Q}_2

[cf. [IUTchIV], Remark 1.10.5, (ii), (iii); [IUTchIV], Remark 2.2.1, (i), (ii)]. Here, we recall from these Remarks in [IUTchIV] [cf. also [Mss]; [vFr], §2] that

This " $\frac{1}{2}$ " in the exponent of h is of interest in light of the existence of sequences of " $abc\ sums$ " for which this " $\frac{1}{2}$ " is **asympototically attained**, i.e., as a **bound from below**, but *only if* one works with abc sums that correspond to elliptic curves whose moduli are **not necessarily compactly bounded**.

This prompts the following question:

Can one construct sequences of abc sums with similar asymptotic behavior, but which correspond to elliptic curves whose moduli are indeed compactly bounded?

At the time of writing, it appears that no definitive answer to this question is known, although there does exist some preliminary work in this direction [cf. [Wada]]. In this context, it is also of interest to recall [cf. the discussion of [IUTchIV], Remark 2.2.1; [vFr], §2] that this " $\frac{1}{2}$ " is **highly reminiscent** of the " $\frac{1}{2}$ " that appears in the **Riemann hypothesis**. So far, in the above discussion, we have restricted ourselves to versions of the Szpiro Conjecture inequality for elliptic curves over NF's that satisfy various technical conditions. On the other hand,

by applying the theory of **noncritical Belyi maps** [cf. the discussion in the final portion of §2.1; [GenEll], Theorem 2.1; [IUTchIV], Corollary 2.3; [IUTchIV], Theorem A] — which may be thought of as a sort of **arithmetic version** of **analytic continuation** [cf. the discussion of §3.3, (vi); [IUTchI], Remark 5.1.4; [IUTchIV], Remark 2.2.4, (iii)] — one may derive the inequalities of the **Vojta/Szpiro/ABC Conjectures** in their usual form.

We refer to [Fsk], §1.3, §2.12, for another — and, in certain respects, more detailed — discussion of these aspects of inter-universal Teichmüller theory. Although a detailed discussion of the somewhat technical, but entirely elementary computation of the left-hand side of the inequality of (ii), (12^{est}), lies beyond the scope of the present paper, we conclude the present (iv) with a summary of the very simple computation of the leading term of the left-hand side of the inequality of (ii), (12^{est}):

· First, one notes [cf. [IUTchIV], Proposition 1.2, (i); [IUTchIV], Proposition 1.3, (i); the second to last display of Step (v) of the proof of [IUTchIV], Theorem 1.10] that, if one *ignores* [since we are only interested in computing the *leading term*!] the *archimedean* valuations of K, as well as the nonarchimedean valuations of K whose ramification index over \mathbb{Q} is "large" [i.e., is \geq the cardinality of the set of nonzero elements of the residue field of the corresponding prime of \mathbb{Q}], then the resulting **log-volume** [suitably normalized!] of the **tensor packet** of **log-shells** corresponding to the **label** $j \in \{1, 2, ..., l^*\}$ is

$$(j+1) \cdot \log(\mathfrak{d}^K)$$

— where we write $\log(\mathfrak{d}^K)$ for the arithmetic degree [suitably normalized, so as to be invariant with respect to finite extensions — cf. [IUTchIV],

Definition 1.9, (i)] of the *arithmetic divisor* determined by the **different** ideal of the number field K over \mathbb{Q} .

On the other hand, the effect — i.e., on the tensor packet of log-shells corresponding to the label j — of multiplying by the **theta value** " $\underline{\underline{q}}^{j^2}$ " [cf. Figs. 3.16, 3.18] at $\underline{\underline{v}} \in \underline{\underline{\mathbb{V}}}^{\mathrm{bad}}$ [cf. the second to last display of Step (v) of the proof of [IUTchIV], Theorem 1.10] is given by

$$-\frac{j^2}{2l} \cdot \log(\mathfrak{q})$$

— where we write $\log(\mathfrak{q})$ for the arithmetic degree [again suitably normal-ized] of the arithmetic divisor determined by the **q-parameters** of the elliptic curve E over F at the valuations that lie over valuations $\in \mathbb{V}^{\text{bad}}_{\text{mod}}$. Thus, the **leading term** of the **log-volume** of the left-hand side of the inequality of (ii), (12^{est}) , is given by

$$\begin{split} \sum_{j=1}^{l^*} \ (j+1) \cdot \log(\mathfrak{d}^K) \ - \ \tfrac{j^2}{2l} \cdot \log(\mathfrak{q}) &\approx \ \tfrac{1}{2} \cdot (\tfrac{l}{2})^2 \cdot \log(\mathfrak{d}^K) \ - \ \tfrac{1}{3 \cdot 2l} \cdot (\tfrac{l}{2})^3 \cdot \log(\mathfrak{q}) \\ &= \ \tfrac{l^2}{8} \cdot \log(\mathfrak{d}^K) \ - \ \tfrac{l^2}{48} \cdot \log(\mathfrak{q}) \\ &= \ \tfrac{l^2}{48} \{ 6 \cdot \log(\mathfrak{d}^K) \ - \ \log(\mathfrak{q}) \} \end{split}$$

— where the notation " \approx " denotes a possible *omission* of terms that do not affect the *leading term*. That is to say, one obtains a "large positive constant" $\frac{l^2}{48}$ times precisely the quantity — i.e.,

$$6 \cdot \log(\mathfrak{d}^K) - \log(\mathfrak{q})$$

— that one wishes to **bound from below** in order to conclude [a suitable version of] the **Szpiro Conjecture inequality**.

As discussed in [IUTchIV], Remark 1.10.1 [cf. also the discussion of §3.9, (i), (ii), below], this "computation of the leading term", which was originally motivated by the scheme-theoretic Hodge-Arakelov theory of [HASurI], [HASurII], was in fact known to the author around the year 2000. Put another way, one of the primary motivations for the development of inter-universal Teichmüller theory was precisely the problem of establishing a suitable framework, or geometry, in which this computation could be performed.

- §3.8. Comparison with the Gaussian integral: At this point, it is of interest to compare and contrast the theory of "arithmetic changes of coordinates" [i.e., §2] and multiradial representations [i.e., the present §3] discussed so far in the present paper with the classical computation of the Gaussian integral, as discussed in §1. In the following, the various "Steps" refer to the "Steps" in the computation of the Gaussian integral, as reviewed in §1.
- (1gau) The naive change of coordinates " $e^{-x^2} \rightsquigarrow u$ " of Step 1 [cf. also Step 2] is formally reminiscent [cf. [IUTchII], Remark 1.12.5, (ii)] of the assignment

$$\{\underline{\underline{q}^{j^2}}\}_{j=1,\dots,l^*} \mapsto \underline{\underline{q}}$$

- that appears in the definition of the Θ -link [cf. §2.4; §3.3, (vii), (b^{Θ}) , (b^q)].
- (2^{gau}) The introduction of **two "mutually alien" copies** of the Gaussian integral in Step 3 may be thought of as corresponding to the appearance of the **two** Θ^{±ell}**NF-Hodge theaters** "•" in the *domain* and *codomain* of the Θ-link [cf. §2.7, (i); Fig. 3.6], which may be thought of as representing two "mutually alien" copies of the **conventional scheme theory** surrounding the elliptic curve under consideration, i.e., the elliptic curve that appears in the *initial* Θ-data of §3.3, (i).
- (3gau) The **two dimensions** of the Euclidean space \mathbb{R}^2 that appears in Step 4 may be thought of as corresponding to the *two dimensions* of the **log-theta-lattice** [cf. §3.3, (ii)], which are closely related to the **two underlying combinatorial dimensions** of a **ring**. Here, we recall from §2.11 that these two underlying combinatorial dimensions of a ring may be understood quite *explicitly* in the case of *NF's*, *MLF's*, or the *field of complex numbers*.
- (4gau) The point of view discussed in Step 5 that integrals may be thought of as computations of **net masses** as *limits of sums of infinitesimals of* **zero mass** may be understood as consisting of *two aspects*: First of all, the *summation of local contributions* that occurs in an integral may be regarded as corresponding to the use of **prime-strips** [i.e., *local data* indexed by elements of <u>V</u> cf. the discussion of §3.3, (iv)] and the computation of **heights** in terms of **log-volumes**, as discussed in §2.2. On the other hand, the *limit* aspect of an *integral*, which involves the consideration of some sort of notion of **infinitesimals** [i.e., "zero mass" objects], may be thought of as corresponding to the **fundamental dichotomy** between **Frobenius-like** and **étale-like** objects [cf. §2.2; §2.7, (ii), (iii); §2.9; §3.3, (iii); §3.4, (i); §3.5].
- (5^{gau}) The generalities concerning the effect on **integrals** of **changes of coordinates** on *local patches* of the *Euclidean plane* in Step 6 may be thought of as corresponding to the generalities on the *computational technique* of **mono-anabelian transport** as a mechanism for computing the effect of "arithmetic changes of coordinates" [cf. the discussion of §2.7, §2.8, §2.9, §2.10, §2.11]. This technique is motivated by the *concrete examples* given in §2.5, §2.6 of *changes of coordinates* related to **positive characteristic Frobenius morphisms**, as well as by the discussion of examples of **finite discrete approximations** of harmonic analysis given in §2.14.
- (6gau) The fundamental examples given in Step 7 of linear changes of coordinates in the Euclidean plane i.e., unipotent linear transformations, toral dilations, and rotations may be thought of as corresponding to the fundamental examples of arithmetic changes of coordinates in the case of MLF's that were discussed in §2.12 [cf. also the discussion of §2.3, §2.4, and §2.13; §3.3, (vi)].
- (7gau) The **passage** from **planar cartesian** to **polar coordinates** discussed in Step 8 may be understood as a sort of **rotation**, or **continuous deformation**, between the **two mutually alien copies** of the Gaussian integral introduced in Step 3, i.e., which correspond to the x- and y-axes. Thus, this passage to polar coordinates may be regarded as corresponding [cf. the discussion at the beginning of §3.1; §3.1, (iv); §3.2; the discussion

sion surrounding Figs. 3.1, 3.3, 3.5, 3.6, 3.12, 3.13, 3.19; the discussion of [IUTchII], Remark 1.12.5] to the "deformation", or "parallel transport", between distinct collections of radial data that appears in the definition of the notion of multiradiality and, in particular, to the passage from the log-theta-lattice to the étale-picture [cf. §3.6, (i)] and, ultimately, to the multiradial representation of §3.7, (i).

(8gau) The fundamental **decoupling** into **radial** and **angular** coordinates discussed in Step 9 may be understood as corresponding to the discussion in §3.4 of **Kummer theory** for **special types** of **functions** via **multiradial decouplings/cyclotomic rigidity** [cf. also the discussion of *unit group* and *value group* portions in §2.11; §3.3, (vii)].

Fig. 3.20.1: Comparison between *inter-universal Teichmüller theory* and the classical computation of the *Gaussian integral*

(9gau) The efficacy of the **change of coordinates** that renders possible the evaluation of the **radial integral** in Step 10 may be understood as an essentially formal consequence of the **quadratic** nature of the **exponent** that appears in the Gaussian distribution. This fundamental aspect of the computation of the Gaussian integral may be regarded as corresponding to the fact that the **rigidity** properties of **mono-theta environments** that underlie the **multiradial decouplings/cyclotomic rigidity** discussed

in §3.4, (iii), (iv) are, in essence, formal consequences [cf. the discussion in the final portion of §3.4, (iv)] of the quadratic structure of the commutators of the theta groups associated to the ample line bundles that appear in the theory [cf. the discussion of [IUTchIII], Remark 2.1.1; [IUTchIV], Remark 2.2.2; the discussion of the functional equation of the theta function in [Pano], §3]. In particular, the evaluation of the radial integral in Step 10 corresponds to the portion of inter-universal Teichmüller theory that relates to the [local] value group portion (b^{Θ}) of the Θ -link [cf. (1^{gau})].

Classical computation of the Gaussian integral	Inter-universal Teichmüller theory
passage from planar cartesian to polar coordinates	passage from the log-theta-lattice to the étale-picture; multiradiality
decoupling into radial and angular coordinates	Kummer theory for functions via multiradial decouplings/ cyclotomic rigidity
evaluation of the radial integral via the quadraticity of the exponent in the Gaussian distribution	multiradiality/ mono-theta rigidity via the quadraticity of theta group commutators; value group portion of the Θ-link
evaluation of the angular integral via the natural logarithm on the complex units	log-shells as containers for Galois evaluation output; iterated rotations/juggling of the log-link acting on [local] units
naive change of coordinates "justifiable" up to a suitable "error factor" $\sqrt{\pi}$ arising from the square root of the angular integral over the complex units	naive approach to bounding heights via "Gaussian Frobenius morphisms" on NF's "justifiable" up to a suitable "log-different error factor" arising from the indeterminacies (Ind1), (Ind2), (Ind3) acting on log-shells

Fig. 3.20.2: Comparison between *inter-universal Teichmüller theory* and the classical computation of the *Gaussian integral*

(10^{gau}) The **angular integral** of Step 11 is an integral over the **unit group** of the field of complex numbers that is evaluated by executing the **change of coordinates** determined by the *imaginary part* of the **natural logarithm**. This *important aspect* of the computation of the Gaussian integral

may be regarded as corresponding to the theory of Galois evaluation and log-shells exposed in §3.6 — cf., especially, the theory involving *iterates* of the log-link discussed in §3.6, (iv). In this context, it is of interest to recall [cf. Example 2.12.3, (v); §3.3, (ii), (vi)] that the log-link may be understood as a sort of arithmetic rotation, or juggling, of the two underlying combinatorial dimensions of a ring that essentially concerns the [local] unit group portion, i.e., (a^{Θ}) , (a^q) , of the Θ -link [cf. §3.3, (vii); §3.6, (iv)].

(11^{gau}) The **final computation** of the Gaussian integral in Step 12 may be summarized [cf. §1.7] as asserting that the **naive change of coordinates** of (1^{gau}) may in fact be "justified", provided that one allows for a suitable "**error factor**" given by the square root of the angular integral of (10^{gau}). This conclusion may be understood as corresponding to the **computation**, discussed in §3.7, (ii), (iii), (iv), of the left-hand side of the inequality of §3.7, (ii), (12^{est}). This computation may be summarized as asserting that one obtains a **bound** on the **height** of the elliptic curve under consideration whose leading term is the "**log-different** $\log(\mathfrak{d}^K)$ " [cf. the final portion of §3.7, (iv)] that one expects from [a suitable version of] the **Szpiro Conjecture**. Put another way, this computation may be summarized as asserting that

the naive approach outlined in §2.3, §2.4 to bounding heights via "Gaussian Frobenius morphisms" on NF's may in fact be "justified", provided that one allows for a suitable "error factor" that arises from the indeterminacies (Ind1), (Ind2), (Ind3) acting on the log-shells — i.e., the [local] unit group portion (a^{Θ}) , (a^q) of the Θ -link [cf. the discussion of (10^{gau})] — that appear in the multiradial representation discussed in §3.7, (i) [cf. also the discussion of [IUTchIV], Remark 2.2.2].

The various observations discussed in the present $\S 3.8$ are summarized in Figs. 3.20.1, 3.20.2, above. Finally, with regard to (1^{gau}) , we note that

the left-hand side " $\{\underline{\underline{q}}^{j^2}\}_{j=1,...,l*}$ " of the assignment discussed in (1^{gau}) cannot be replaced by

"
$$\underline{\underline{q}}^{\lambda}$$
" for $1 \neq \lambda \in \mathbb{Q}_{>0}$

or by

"
$$\{\underline{\underline{q}^{N \cdot j^2}}\}_{j=1,...,l^*}$$
" for $2 \le N \in \mathbb{N}$.

Indeed, this property of the left-hand side of the assignment discussed in (1^{gau}) is, in the case of " \underline{q} ", a consequence of the

• the lack [i.e., in the case of " $\underline{\underline{q}}^{\lambda}$ "] of a theory of multiradial decouplings/cyclotomic rigidity of the sort [cf. the discussion of §3.4, (iii), (iv)] that exists in the case of **theta functions** and **mono-theta environments**

[cf. the discussion of [IUTchIII], Remark 2.2.2, (i), (ii), (iii)] and, in the case of " $\{\underline{q}^{N \cdot j^2}\}_{j=1,...,l*}$ ", a consequence of the

- · special role [cf. the discussion of §3.4, (iii)] played by the **first power** of [reciprocals of l-th roots of the] **theta function**;
- the condition [cf. the discussion at the beginning of $\S 3.6$] that the assignment "abstract functions \mapsto values" that occurs in the passage from theta functions to theta values be obtained by applying the technique of Galois evaluation

[cf. [IUTchII], Remark 3.6.4, (iii), (iv); [IUTchIII], Remark 2.1.1, (iv); the discussion of the final portion of Step (xi) of the proof of [IUTchIII], Corollary 3.12]. Moreover, the negation of this property of the left-hand side of the assignment discussed in (1^{gau}) would imply a stronger version of the Szpiro Conjecture inequality that is in fact false [cf. [IUTchIV], Remark 2.3.2, (ii)]. By contrast,

the **right-hand side** " \underline{q} " of the assignment discussed in (1^{gau}) **can** be **replaced** by " \underline{q} " for $1 \neq \lambda \in \mathbb{Q}_{>0}$, without any substantive effect on the theory; moreover, doing so does **not** result in **any substantive improvement** in the estimates discussed in §3.7, (ii), (iii), (iv)

[cf. [IUTchIII], Remark 3.12.1, (ii)]. In this context, it is of interest to observe that:

This sort of qualitative difference between the left- and right- hand sides of the assignment $\{\underline{q}^{j^2}\}_{j=1,\dots,l^*} \mapsto \underline{q}$ is reminiscent of the qualitative difference — e.g., the presence or absence of the exponential! — between the left- and right- hand sides of the naive change of coordinates $e^{-x^2} \rightsquigarrow u$.

- §3.9. Relation to scheme-theoretic Hodge-Arakelov theory: Finally, we pause to reconsider the theory of multiradial representations developed in the present §3 from the point of view of the scheme-theoretic Hodge-Arakelov theory discussed in Example 2.14.3 a theory which, as discussed in the final portion of §3.7, (iv), played a *central role* in motivating the development of interuniversal Teichmüller theory.
- (i) <u>Hodge filtrations and theta trivializations</u>: We begin by examining the natural isomorphism of F-vector spaces of dimension l^2

$$\Gamma(E^{\dagger}, \mathcal{L}|_{E^{\dagger}})^{< l} \stackrel{\sim}{\to} \mathcal{L}|_{E[l]}$$

that constitutes the **fundamental theorem of Hodge-Arakelov theory** discussed in Example 2.14.3 in a bit more detail [cf., e.g., the discussion surrounding [Pano], Theorem 1.1] in the case where F is an **NF**. First of all, we observe that, although both the domain and codomain of this isomorphism are F-vector spaces of dimension l^2 , by considering the natural action of suitable theta groups on the domain and codomain and applying the well-known theory of irreducible representations of theta groups, one may conclude that, up to "uninteresting redudancies", this isomorphism may in fact be ["essentially"] regarded as an isomorphism between F-vector spaces of dimension l. The left-hand side of this isomorphism of l-dimensional F-vector spaces admits a natural **Hodge filtration** that arises by considering the subspaces of relative degree l for the cotangent space of l at the origin of l, we write l for the cotangent space of l at the origin of l.

and τ_E for the dual of ω_E , then the adjacent subquotients of this Hodge filtration are the 1-dimensional F-vector spaces

$$au_E^{\otimes t}$$

for $t=0,\ldots,l-1$, tensored with some fixed 1-dimensional F-vector space [i.e., which is independent of t], which we shall ignore since its arithmetic degree [i.e., when regarded as being equipped with natural integral structures at the nonarchimedean valuations of F and natural Hermitian structures at the archimedean valuations of F] is sufficiently small that its omission does not affect the computation of the leading terms of interest. On the other hand, the right-hand side of the isomorphism under consideration admits a natural theta trivialization [i.e., a natural isomorphism with the F-vector space $F^{\oplus l}$ given by the direct sum of l copies of the F-vector space F, which we think of as being labeled by $t=0,\ldots,l-1$], which is compatible — up to contributions that are sufficiently small as to have no effect on the computation of the leading terms of interest — with the various natural integral structures and natural Hermitian metrics involved, except at the valuations where E has potentially multiplicative reduction, where one must adjust the natural integral structure [i.e., the integral structure determined by the ring of integers \mathcal{O}_F of F] on the copy of F in $F^{\oplus l}$ labeled $t \in \{0,\ldots,l-1\}$ by a factor of

$$\underline{q}^{t^2/4}$$

— where the notation " \underline{q} " denotes a 2l-th root of the q-parameter of E at the valuation under consideration. Next, let us observe that [again up to contributions that are sufficiently small as to have no effect on the computation of the leading terms of interest] one may replace the label $t \in \{0, \ldots, l-1\}$ by a label $j \in \{1, \ldots, l^*\}$, where we think of t as $\approx 2j$. Write $\Omega_E^{\log \det} \subseteq \omega_E^{\otimes 2}$. Then the 1-dimensional F-vector spaces — i.e., which we think of as arithmetic line bundles by equipping these 1-dimensional F-vector spaces with natural integral structures and natural Hermitian metrics — corresponding to the label $j \in \{1, \ldots, l^*\}$ on the left- and right-hand sides of the natural isomorphism of l-dimensional F-vector spaces determined by the fundamental theorem of Hodge-Arakelov theory assume the form

$$\{(\Omega_E^{\log})^{\otimes j}\}^\vee, \quad \underline{q}^{j^2} \cdot F$$

— where the notation " \vee " denotes the dual. Put another way, if we tensor the dual of the left-hand side contribution at $j \in \{1, ..., l^*\}$ with the right-hand side contribution at $j \in \{1, ..., l^*\}$, then we obtain the conclusion that the natural isomorphism under consideration may be thought of "at a very rough level" — i.e., by replacing the Hodge filtration with its semi-simplification, etc. — as a sort of

global section of some sort of **weighted average** over j of the [arithmetic line bundles corresponding to the] 1-dimensional F-vector spaces

$$\underline{q}^{j^2} \cdot (\Omega_E^{\log})^{\otimes j}$$

— where j ranges over the elements of $\{1, \ldots, l^*\}$.

In fact, the above discussion may be translated into *purely geometric terms* by working with the **tautological one-dimensional semi-abelian scheme** over the **natural compactification of the moduli stack of elliptic curves** [over,

say, a field of characteristic zero]. Then " Ω_E^{\log} " may be thought of as the line bundle of **logarithmic differentials** on this compactified moduli stack. Moreover, one can *compute global degrees* " $\deg(-)$ "

$$\begin{split} \sum_{j=1}^{l^*} \ \deg((\Omega_E^{\log})^{\otimes j}) \ - \ \deg(\frac{j^2}{2l} \cdot [\infty]) &= \ \sum_{j=1}^{l^*} \ j \cdot \deg(\Omega_E^{\log}) \ - \ \frac{j^2}{2l} \cdot \deg([\infty]) \\ &\approx \ \frac{1}{2} \cdot (\frac{l}{2})^2 \cdot \deg(\Omega_E^{\log}) \ - \ \frac{1}{3 \cdot 2l} \cdot (\frac{l}{2})^3 \cdot \deg([\infty]) \\ &= \ \frac{l^2}{8} \cdot \deg(\Omega_E^{\log}) \ - \ \frac{l^2}{48} \cdot \deg([\infty]) \\ &= \ \frac{l^2}{48} \{ \deg((\Omega_E^{\log})^{\otimes 6}) \ - \ \deg([\infty]) \} \end{split}$$

— where the notation " \approx " denotes a possible *omission* of terms that do not affect the *leading term*; " $[\infty]$ " denotes the effective divisor on the compactified moduli stack under consideration determined by the *point at infinity*, i.e., the scheme-theoretic zero locus of the *q*-parameter; by abuse of notation, we use the same notation for "*compactified moduli stack versions*" of the corresponding objects introduced in the discussion of elliptic curves over NF's. That is to say, in summary,

the **determinant** of the **natural isomorphism** that appears in the **fundamental theorem of Hodge-Arakelov theory** is simply [an invertible constant multiple of] some positive tensor power of the well-known **discriminant modular form** of weight 12, i.e., a global section of $\omega_E^{\otimes 12} = (\Omega_E^{\log})^{\otimes 6}$ whose unique zero is a zero of order 1 at the *point at infinity* of the compactified moduli stack of elliptic curves

[cf. [Pano], §1; the discussion of the final portion of [HASurI], §1.2, for more details].

- (ii) <u>Comparison with inter-universal Teichmüller theory:</u> First, we begin with the observation that, relative to the *classical analogy* between *NF's* and *one-dimensional functions fields* [over some field of constants], it is natural to think of
 - · **log-shells** as *localized absolute arithmetic analogues* of the notion of the sheaf of **logarithmic differentials**.

Indeed, this point of view is supported by the fact that the log-shell associated to a finite extension of \mathbb{Q}_p [for some prime number p] whose absolute ramification index is $\leq p-2$ coincides with the dual fractional ideal to the different ideal of the given finite extension of \mathbb{Q}_p [cf. [IUTchIV], Proposition 1.2, (i); [IUTchIV], Proposition 1.3, (i)]. Thus, it is natural to regard

· the [arithmetic line bundle corresponding to the] 1-dimensional F-vector space

$$q^{j^2} \cdot (\Omega_E^{\log})^{\otimes j}$$

- where j ranges over the elements of $\{1, \ldots, l^*\}$ of the discussion of (i) as a sort of **scheme-theoretic analogue**, or **precursor**, of the portion labeled by j of the **multiradial representation** discussed in §3.7, (i) [cf. also the explicit display of §3.7, (ii), (8^{est})];
- · the resulting computation of global degrees "deg(-)" given in (i) as a sort of **scheme-theoretic analogue**, or **precursor**, of the computation of the

leading term of the log-volume of the left-hand side of the inequality of $\S3.7$, (ii), (12^{est}) [cf. the final portion of $\S3.7$, (iv)].

Indeed, this was precisely the point of view of the author around the year 2000 that motivated the author to develop inter-universal Teichmüller theory.

(iii) Analytic torsion interpretation: In conventional Arakelov theory for varieties over NF's, analytic torsion refers to a metric invariant, at the archimedean valuations of an NF, that measures the way in which the space of global [holomorphic/algebraic sections of a line bundle — which is regarded, by means of various considerations in harmonic analysis, as a subspace of the Hilbert space of L^2 -class sections of the line bundle — is embedded inside this ambient Hilbert space of L^2 -class sections.

Since this ambient Hilbert space of L^2 -class sections may be regarded as a topological invariant, i.e., which is unaffected by deformations of the holomorphic moduli of the variety under consideration, the notion of analytic torsion may be understood as a measure of the way in which the subspace constituted by the space of global algebraic sections — which depends, in a quite essential fashion, on the holomorphic moduli of the variety under consideration — is embedded inside this topological invariant.

When formulated in this way,

the notion of analytic torsion becomes highly reminiscent of the computational technique of mono-analytic transport [cf. the discussion of §2.7, §2.9] and, in particular, of the use of log-shells to construct the "multiradial containers" [cf. the discussion of §3.6, (iv)] for the various arithmetic holomorphic structures that appear in the multiradial representation discussed in §3.7, (i).

Indeed, from this point of view, scheme-theoretic Hodge-Arakelov theory may be understood as a sort of *intermediate step*—i.e., a **finite discrete approximation**, in the spirit of the discussion of §2.14, which is, moreover, [unlike the classical notion of analytic torsion! defined over NF's — between the classical notion of analytic torsion and inter-universal Teichmüller theory. Put another way,

- the natural isomorphism that appears in the fundamental theorem of scheme-theoretic Hodge-Arakelov theory may be understood as a sort of polynomial-theoretic discretization of the theory surrounding the classical notion of analytic torsion, while
- · inter-universal Teichmüller theory may be understood as a sort of global Galois-theoretic version over NF's of the theory surrounding the classical notion of analytic torsion

[cf. the discussion of [IUTchIV], Remark 1.10.4].

Section 4: Historical comparisons and analogies

Numerous connections to classical theories: Many discussions of inter-universal Teichmüller theory exhibit a tendency to emphasize the novelty of many of the *ideas* and *notions* that constitute the theory. On the other hand, another important aspect of many of these ideas and notions of inter-universal Teichmüller theory is their quite substantial relationship to *numerous classical theories*. One notable consequence of this latter aspect of inter-universal Teichmüller theory is the following:

one obstacle that often hampers the progress of mathematicians in their study of inter-universal Teichmüller theory is a **lack of familiarity** with such **classical theories**, many of which date back to the 1960's or 1970's [or even earlier]!

(i) <u>Contrast with classical numerical computations</u>: We begin our discussion by recalling

the famous computation in the late nineteenth century by William Shanks of π to 707 places, which was later found, with the advent of digital computing devices in the twentieth century, to be correct only up to 527 places!

The work that went into this sort of computation may strike some mathematicians as being reminiscent, in a certain sense, of the *sheer number of pages* of the various papers — i.e., such as [Semi], [FrdI], [FrdII], [EtTh], [GenEll], [AbsTopIII], [IUTchII], [IUTchII], [IUTchIII], [IUTchIII], [IUTchIV] — that one must study in order to achieve a thorough understanding of inter-universal Teichmüller theory. In fact, however, inter-universal Teichmüller theory differs quite *fundamentally* from the computation of Shanks in that, as was discussed throughout the present paper, and especially in §3.8, the *central ideas* of inter-universal Teichmüller theory are rather **compact** and **conceptual** in nature and revolve around the issue of

comparison, by means of the notions of mono-anabelian transport and multiradiality, of mutually alien copies of miniature models of conventional scheme-theory in a fashion that exhibits remarkable similarities to the *compact* and *conceptual* nature of the classical computation of the Gaussian integral by means of the introduction of two "mutually alien copies" of this integral.

In this context, it is of interest to recall the remarkable similarities of certain aspects of inter-universal Teichmüller theory to the theory surrounding the functional equation of the theta function — i.e., "Jacobi's identity" [cf. the discussion of the final portion of [Pano], §3; the discussion preceding [Pano], Theorem 4.1] — which may be thought of as a sort of function-theoretic version of the computation of the Gaussian integral that may be obtained, roughly speaking, by interpreting this computation of the Gaussian integral in the context of the hyper-bolic geometry of the upper half-plane. As discussed in §2.4; Example 3.2.1, (iii); §3.3, (v), the analogy between certain aspects of inter-universal Teichmüller theory and the hyperbolic geometry of the upper half-plane has not been exposed in the present paper in much detail since it has already been exposed in substantial detail in [BogIUT]. On the other hand, it is of interest to recall that classically,

Jacobi's identity was often appreciated as a relatively *compact* and *conceptual* way to achieve a **startling improvement** in **computational accuracy** in the context of **explicit numerical calculations** of **values** of the **theta function**

[cf. the discussion preceding [Pano], Theorem 4.1].

- (ii) <u>Explicit examples of connections to classical theories:</u> Next, we review various explicit examples of *connections* between inter-universal Teichmüller theory, as exposed thus far in the present paper, and various *classical theories*:
- (1^{cls}) Recall from the discussion of §2.10 that the notion of a "universe", as well as the use of multiple universes within the discussion of a single set-up in arithmetic geometry, already occurs in the mathematics of the 1960's, i.e., in the mathematics of Galois categories and étale topoi associated to schemes [cf. [SGA1], [SGA4]].
- (2^{cls}) One important aspect of the appearance of *universes* in the theory of **Galois categories** is the **inner automorphism indeterminacies** that occur when one relates Galois categories associated to distinct schemes via a morphism between such schemes [cf. [SGA1], Exposé V, §5, §6, §7]. These indeterminacies may be regarded as **distant ancestors**, or **prototypes**, of the more *drastic* indeterminacies cf., e.g., the indeterminacies (Ind1), (Ind2), (Ind3) discussed in §3.7, (i) that occur in inter-universal Teichmüller theory.
- (3^{cls}) The theory of *Tate* developed in the 1960's [cf. [Serre], Chapter III, Appendix] concerning **Hodge-Tate representations** plays a fundamental role in the theory of $[\mathbb{Q}_pGC]$ [cf. also [AbsTopI], §3]. This theory of $[\mathbb{Q}_pGC]$ and [AbsTopI], §3, may be regarded as a precursor of the theory of log-shells developed in [AbsTopIII], §3, §4, §5.
- (4^{cls}) The approach of Faltings to **p-adic Hodge theory** via the technique of almost étale extensions [cf. [Falt2]] plays a central role in the **p-adic anabelian geometry** developed in [pGC]. Here, we recall that this theory of [pGC] constitutes the crucial technical tool that underlies the **Belyi** and **elliptic cuspidalizations** of [AbsTopII], §3, which, in turn, play a quite essential role in the theory of [AbsTopIII], hence, in particular, in inter-universal Teichmüller theory.
- (5^{cls}) The work of *Tate* in the 1960's concerning **theta functions** on uniformizations of **Tate curves** [cf. [Mumf2], §5] plays a *fundamental role* in [EtTh], hence also in inter-universal Teichmüller theory.
- (6^{cls}) The **scheme-theoretic Hodge-Arakelov theory** discussed in Example 2.14.3 and §3.9 may be regarded as a *natural extension* of [the portion concerning *elliptic curves* of] *Mumford's* theory of **algebraic theta functions** [cf. [Mumf1]].
- (7^{cls}) The **invariance of the étale site**, up to isomorphism, with respect to the **Frobenius morphism in positive characteristic** [cf. the discussion of Example 2.6.1, (i)] was well-known [cf. [SGA1], Exposé IX, Théorème 4.10] to the Grothendieck school in the 1960's. As discussed in §2.6, §2.7, this phenomenon, taken together with the *fundamental work* of *Uchida* [cf. [Uchi]] in the 1970's concerning the **anabelian geometry** of one-dimensional function fields over a finite field, may be regarded as the *fundamental prototype* for the apparatus of **mono-anabelian transport**—and, in particular, for the terms "**Frobenius-like**" and "**étale-like**"
 - which plays a *central role* in inter-universal Teichmüller theory.
- (8^{cls}) The use of **abstract** [commutative] monoids, e.g., in the theory of **Frobenioids** [cf. §3.3, (iii); §3.5], which plays a fundamental role in inter-

- universal Teichmüller theory, was motivated by the use of such monoids in the theory of **log schemes** [cf. [Kato1], [Kato2]], which, in turn, was motivated by the use of such monoids in the classical theory of **toric varieties** developed in the 1970's [cf. [KKMS]].
- (9^{cls}) Recall from the discussion of §3.1, (iv), that the notion of **multiradiality**, which plays a fundamental role in inter-universal Teichmüller theory, may be regarded as a sort of abstract combinatorial analogue of the **Grothen-dieck definition** of a **connection**, i.e., which plays a central role in the classical theory of the **crystalline site** and dates back to the 1960's [cf. [GrCrs]].
- (iii) Monoids and Galois theory: With regard to (ii), (8^{cls}), we observe that the important role played by abstract [commutative] monoids in inter-universal Teichmüller theory is reminiscent of the way in which such monoids are used by many mathematicians in research related to "geometry over \mathbb{F}_1 " [i.e., the fictitious "field with one element"]. On the other hand, the way in which such monoids are used in inter-universal Teichmüller theory differs fundamentally from the way in which such monoids are used in conventional research on geometry over \mathbb{F}_1 in the following respect:
 - · in inter-universal Teichmüller theory, various anabelian and Kummertheoretic aspects of Galois or arithmetic fundamental groups that act on such monoids play a fundamental role [cf. the discussion of monoanabelian transport in §2.7, §2.9!];
 - · by contrast, at least to the author's knowledge at the time of writing, research on geometry over \mathbb{F}_1 does not involve, in any sort of essential way, such anabelian or Kummer-theoretic aspects of Galois or arithmetic fundamental groups acting on monoids.

Indeed, this fundamental difference between inter-universal Teichmüller theory and conventional research on geometry over \mathbb{F}_1 might give rise to various interesting questions and hence stimulate further research.

- (iv) <u>Techniques to avoid stacks and 2-categories</u>: Some mathematicians have a *strong aversion* to the use of such notions as "categories of categories" or algebraic stacks i.e., notions that obligate one to work with **2-categories** in arithmetic geometry. Here, we observe that the substantive mathematical phenomenon that obligates one, in such situations, to work with 2-categories is essentially the same phenomenon as the phenomenon constituted by the **inner automorphism indeterminacies** discussed in (ii), (2^{cls}). On the other hand, in inter-universal Teichmüller theory, various "general nonsense" techniques are applied that allow one, in such situations, to work with **categories** [i.e., as opposed to 2-categories] and thus avoid the cumbersome complications that arise from working with 2-categories:
 - · In inter-universal Teichmüller theory, one typically works with **slim categories** such as Galois categories that arise from *slim profinite groups* [i.e., profinite groups for which the centralizer of every open subgroup is trivial] or *temp-slim tempered groups* [cf. [Semi], Remark 3.4.1]. The use of slim categories allows one, in effect, to think of "categories of categories" as

categories [i.e., rather than 2-categories]. Indeed, in the case of slim profinite groups, this point of view is precisely the point of view that underlies the theory of [GeoAnbd]. Generalities concerning slim categories may be found in [FrdI], Appendix.

· Another important "general nonsense" technique that is used in interuniversal Teichmüller theory to keep track explicitly of the various types of **indeterminacies** that occur is the notion of a **poly-morphism** [cf. [IUTchI], §0], i.e., a [possibly empty] subset of the set of arrows between two objects in a category. Thus, there is a natural way to compose two poly-morphisms [i.e., that consist of composable arrows] to obtain a new poly-morphism. Consideration of such composites of poly-morphisms allows one to trace how various indeterminacies interact with one another.

In this context, it is perhaps useful to observe that, from a more classical point of view,

the inner automorphism indeterminacies discussed in (ii), (2^{cls}) , correspond to the indeterminacy in the choice of a **basepoint** of a [say, connected, locally contractible] **topological space**.

That is to say, in anabelian geometry, working with

slim anabelioids as opposed to slim profinite groups

corresponds, in essence, to working, in classical topology, with

topological spaces as opposed to pointed topological spaces.

Since many natural maps between topological spaces — i.e., such as **localization** maps! — are not compatible with choices of distinguished points, it is often more natural, in many discussions of classical topology, to make use [not only of the notion of a "pointed topological space", but also] of the notion of a "topological space" [i.e., that is not equipped with the choice of a distinguished point!]. It is precisely for this reason that in many discussions — i.e., such as those that occur in inter-universal Teichmüller theory, for instance, in the case of **localizations** at various **primes of an NF**! [cf. the discussion of §3.3, (iv), (v), (vi)] — involving the geometry of categories, it is much more natural and less cumbersome to work with slim categories such as slim anabelioids [i.e., as opposed to profinite groups].

- §4.2. Contrasting aspects of class field theory and Kummer theory: We begin our discussion by observing that the role played by local class field theory [cf. the discussion of §2.11; §2.12, especially Example 2.12.1, (ii), (iii); §3.4, (v)] in inter-universal Teichmüller theory is, in many respects, not particularly prominent, while global class field theory [for NF's] is entirely absent from inter-universal Teichmüller theory. This situation for class field theory contrasts sharply with the very central role played by Kummer theory in inter-universal Teichmüller theory [cf. the discussion of mono-anabelian transport in §2.7, §2.9!]. In fact, this state of affairs is both natural and indeed somewhat inevitable for a number of reasons, which we pause to survey in the discussion to follow [cf. also Fig. 4.1 below].
- (i) Strong functoriality properties and the central role of cyclotomic rigidity in Kummer theory: Perhaps the most conspicuous difference between class field theory and Kummer theory is the fact that, whereas

- · class field theory may only be formulated for very special types of fields, e.g., for global fields such as NF's or one-dimensional function fields over finite fields or for localizations of such global fields,
- **Kummer theory**, by contrast, may be formulated, by using the *Kummer exact sequence* in étale cohomology [cf., e.g., the discussion at the beginning of [Cusp], §2], for [essentially] **arbitrary** types of schemes and even for **abstract monoids** [cf. [FrdII], Definition 2.1, (ii)] that satisfy relatively weak conditions and do not necessarily arise from the multiplicative structure of a commutative ring.

A closely related difference between class field theory and Kummer theory is the fact that, whereas

- · class field theory only satisfies very limited functoriality properties, i.e., for finite separable field extensions and localizations of global fields,
- · **Kummer theory** satisfies **very strong functoriality** properties, for [essentially] *arbitrary morphisms* between [essentially] *arbitrary schemes* or between *abstract monoids* that satisfy suitable, relatively weak conditions.

These properties of Kummer theory make

Kummer theory much more suitable for use in anabelian geometry, where it is natural to consider morphisms between arithmetic fundamental groups that correspond to quite *general morphisms* between quite *general schemes*, i.e., where by "quite general", we mean *by comparison* to the restrictions that arise if one attempts to apply class field theory.

Perhaps the *most fundamental example* of this sort of situation [i.e., that is of interest in anabelian geometry, but to which class field theory cannot, at least in any immediate way, be applied] is the situation that arises if one considers the operation of

evaluation of various types of functions on, say, a curve, at a closed point of the curve

[cf. the discussion of (ii) below; Example 2.13.1, (iv); §2.14; §3.6; [IUTchIV], Remark 2.3.3, (vi)]. On the other hand, one *highly nontrivial* and *quite delicate* aspect of *Kummer theory* that does *not* appear in *class field theory* is the issue of

establishing **cyclotomic rigidity isomorphisms** between *cyclotomes* constructed from the various *rings*, *monoids*, *Galois groups*, *or arithmetic* fundamental groups that appear in a particular situation.

Various examples of such isomorphisms between cyclotomes may be seen in the theory discussed in [PrfGC], [the discussion preceding] Lemma 9.1; [AbsAnab], Lemma 2.5; [Cusp], Proposition 1.2, (ii); [FrdII], Theorem 2.4, (ii); [EtTh], Corollary 2.19, (i); [AbsTopIII], Corollary 1.10, (ii); [AbsTopIII], Remarks 3.2.1, 3.2.2 [cf. also Example 2.12.1, (ii); Example 2.13.1, (ii); §3.4, (ii), (iii), (iv), (v), of the present paper]. All of these examples concern "Kummer-faithful" situations [cf. [AbsTopIII], Definition 1.5], i.e., situations in which

the **Kummer map** on the multiplicative monoid [e.g., which arises from the multiplicative structure of a ring] of interest is **injective**.

Then the cyclotomic rigidity issues that arise typically involve the cyclotomes obtained by considering the torsion subgroups of such multiplicative monoids. This sort of situation contrasts sharply with the sort of highly "non-Kummer-faithful" situation considered in [PopBog], i.e., where one works with function fields over algebraic closures of finite fields [cf. [PopBog], Theorem I]. That is to say, in the sort of situation considered in [PopBog], the Kummer map vanishes on the roots of unity of the base field, and the Kummer theory that is applied [cf. [PopBog], §5.2] does not revolve around the issue of establishing cyclotomic rigidity isomorphisms.

(ii) The functoriality of Kummer theory with respect to evaluation of special functions at torsion points: As mentioned in (i), the operation of evaluation of various types of [special] functions on, say, a curve, at various types of [special] points of the curve plays a fundamental role in the Kummer theory that is applied in inter-universal Teichmüller theory [cf. the discussion of Example 2.13.1, (iv); §2.14; §3.6; [IUTchIV], Remark 2.3.3, (vi)]. This contrasts sharply with the fact that

class field theory may only be related to the operation of evaluation of special functions at special points in very restricted classical cases, namely, the theory of exponential functions in the case of \mathbb{Q} or modular and elliptic functions in the case of imaginary quadatic fields.

Indeed, the goal of generalizing the theory that exists in these very restricted cases to the case of **arbitrary NF's** is precisely the content of *Kronecker's Jugendtraum*, or *Hilbert's twelfth problem* [cf. the discussion of [IUTchIV], Remark 2.3.3, (vii)]. Indeed, in light of this state of affairs, one is tempted to regard **inter-universal Teichmüller theory** as a sort of

"realization/solution" of the "version" of Kronecker's Jugendtraum, or Hilbert's twelfth problem, that one obtains if one replaces class field theory by Kummer theory!

- (iii) The arithmetic holomorphicity of global class field theory versus the mono-analyticity of Kummer theory: Another important aspect of the fundamental differences between class field theory and Kummer theory that were highlighted in the discussion of (i) is the following:
 - · whereas the essential content of **class field theory** reflects various delicate arithmetic properties that are closed related to the **arithmetic** holomorphic structure of the very restricted types of arithmetic fields to which it may be applied,
 - · the very general and strongly functorial nature of Kummer theory makes Kummer theory more suited to treating the sorts of mono-analytic structures that arise in inter-universal Teichmüller theory

[cf. the discussion of §2.7, (vii)]. Indeed, at a very naive level, this phenomenon may be seen in the difference between the "input data" for class field theory and Kummer theory, i.e., very restricted arithmetic fields in the case of class field theory versus very general types of abstract multiplicative monoids in the case of Kummer theory [cf. the discussion of (i)]. Another important instance of this phenomenon may be seen in the fact that whereas

- theory for NF's, involves a nontrivial "intertwining" relationship, for any prime number l, between the local unit determined by l at nonarchimedean valuations of residue characteristic $\neq l$ and the nonzero element of the value group determined by l at nonarchimedean valuations of residue characteristic l,
- · the *compatibility* of the **Kummer theory** applied in inter-universal Teichmüller theory with various "splittings"/"decouplings" between the local **unit group** and **value group** portions of this Kummer theory plays a *central role* in inter-universal Teichmüller theory
- cf. the discussion of §3.4; §3.8, (8^{gau}); [IUTchIV], Remark 2.3.3, (v). A closely related fact is the fact that such local unit group/value group splittings are **incompatible** with [the multiplicative version of] **Hilbert's Theorem 90**, which plays a central role in **class field theory**: that is to say, in the notation of Examples 2.12.1, 2.12.2, one verifies immediately that whereas $H^1(G_k, \overline{k}^{\times}) = 0$,

$$H^1(G_k, \boldsymbol{\mu}_{\overline{k}}) \neq 0, \quad H^1(G_k, \mathcal{O}_{\overline{k}}^{\times}) \neq 0, \quad H^1(G_k, \boldsymbol{\mu}_{\overline{k}} \cdot \pi_k^{\mathbb{Q}}) \neq 0$$

- where we write $\mu_{\overline{k}} \cdot \pi_k^{\mathbb{Q}} \subseteq \overline{k}^{\times}$ for the subgroup of elements for which *some positive* $power \in \pi_k^{\mathbb{Z}}$. Finally, we recall from the discussion of [IUTchIV], Remark 2.3.3, (i), (ii), (iv), that a sort of *analytic number theory* version of this phenomenon may be seen in the fact that whereas
 - · **class field theory** is closely related especially if one takes the point of view of *early approaches* to class field theory such as the approach attributed to *Weber* to the "**coherent aggregrations**" of primes that appear in discussions of the **Dirichlet density** of primes, e.g., in the context of the **Tchebotarev density theorem**,
 - the **Kummer-theoretic** approach of inter-universal Teichmüller theory gives rise to the **multiradial representation** discussed in §3.7, (i), which leads to *log-volume estimates* [cf. the discussion of §3.7, (ii), (iv); the application of [IUTchIV], Proposition 1.6, and [IUTchIV], Proposition 2.1, (ii), in the explicit calculations of [IUTchIV], §1, §2] that involve, in an essential way, the **Prime Number Theorem**, i.e., which, so to speak, counts primes "one by one", in effect "deactivating the coherent aggregrations of primes" that appear in discussions of the Dirichlet density of primes.
- (iv) Global reciprocity law versus global cyclotomic rigidity: Finally, we recall from the discussion of ["(b-4)" in] [IUTchIV], Remark 2.3.3, (i), (ii), that
 - the use of **cyclotomic extensions** in classical approaches to verifying the **global reciprocity law** in **class field theory** for NF's, i.e., to verifying that, in effect, the *reciprocity map vanishes* on idèles that arise from elements of the NF under consideration,

may be thought of as corresponding to

• the approach taken in inter-universal Teichmüller theory to constructing cyclotomic rigidity isomorphisms for the Kummer theory related to NF's [cf. §3.4, (ii), (v)], i.e., in effect, by applying the elementary

fact that $\mathbb{Q}_{>0} \cap \widehat{\mathbb{Z}}^{\times} = \{1\}$ [cf. the discussion of the latter portion of [IUTchIII], Remark 3.12.1, (iii)].

Indeed, both of these phenomena concern the fact that some version of the **product** formula — that is to say, which, a priori [or from a more naive, elementary point of view], is only known to hold for the Frobenius-like multiplicative monoids that arise from NF's — in fact holds [i.e., in the form of the global reciprocity law or the elementary fact that $\mathbb{Q}_{>0} \cap \widehat{\mathbb{Z}}^{\times} = \{1\}$] at the level of [étale-like!] **profinite** Galois groups.

Class field theory	Kummer theory
may be formulated only for special arithmetic fields	may be formulated for very general abstract multiplicative monoids
satisfies only very limited functoriality properties	satisfies very strong functoriality properties
limited range of applicability to anabelian geometry	wide range of applicability to anabelian geometry
cyclotomic rigidity isomorphisms are irrelevant	cyclotomic rigidity isomorphisms play a central role
no known compatibility with evaluation of functions at points	compatible with evaluation of functions at points
closely related to the arithmetic holomorphic structure of very restricted types of arithmetic fields	applicable to mono-analytic structures such as abstract multiplicative monoids
incompatible with local unit group/value group decouplings	compatible with local unit group/ value group decouplings
related to global Dirichlet density of primes	naturally applied in conjunction with Prime Number Theorem
verification, involving cyclotomic extensions, of the global reciprocity law	global cyclotomic rigidity algorithms via $\mathbb{Q}_{>0} \ \bigcap \ \widehat{\mathbb{Z}}^{\times} \ = \ \{1\}$

Fig. 4.1: Comparison between class field theory and Kummer theory

§4.3. Arithmetic and geometric versions of the Mordell Conjecture:

(i) Rough qualitative connections with Faltings' proof of the Mordell Conjecture: First, we begin by observing [cf. [IUTchIV], Remark 2.3.3, (i), (ii), for more details] that there are numerous rough, qualitative correspondences—some of which are closely related to the topics discussed in §4.1 and §4.2—

between various components of the proof of the Mordell Conjecture given in [Falt1] and inter-universal Teichmüller theory:

- (1^{flt}) Various well-known aspects of classical algebraic number theory related to the "geometry of numbers", such as the theory of heights and the Hermite-Minkowski theorem, are applied in [Falt1]. Similar aspects of classical algebraic number theory may be seen in the "non-interference" property [i.e., the fact that the only nonzero elements of an NF that are integral at all nonarchimedean and archimedean valuations of the NF are the roots of unity] for copies of the number field $F_{\rm mod}$ discussed in §3.7, (i), as well as in the use of global realified Frobenioids associated to NF's [i.e., which are essentially an abstract category-theoretic version of the classical notions of arithmetic degrees and heights].
- (2^{flt}) **Global class field theory** for NF's, as well as the closely related notion of **Dirichlet density of primes**, plays an important role in [Falt1]. These aspects of [Falt1] are compared and contrasted in substantial detail in the discussion of §4.2 with the *Kummer theory* that plays a central role in inter-universal Teichmüller theory.
- (3^{flt}) The theory of **Hodge-Tate decompositions** of p-adic Tate modules of abelian varieties over MLF's plays an important role both in [Falt1] and, as discussed in §4.1, (ii), (4^{cls}), in inter-universal Teichmüller theory.
- (4^{flt}) The computations, applied in [Falt1], of the ramification that occurs in the theory surrounding **finite flat group schemes** bear a rough resemblance to the ramification computations involving *log-shells* in [AbsTopIII]; [IUTchIV], Propositions 1.1, 1.2, 1.3, 1.4.
- (5^{flt}) The hidden endomorphisms [cf. the discussion of [AbsTopII], Introduction] that underlie the theory of Belyi and elliptic cuspidalizations [cf. the discussion of §3.3, (vi); §3.4, (iii)], which play an important role in interuniversal Teichmüller theory, as well as the theory of noncritical Belyi maps that is applied [cf. the discussion of §3.7, (iv)], via [GenEll], §2, in [IUTchIV], §2, may be thought of as a sort of analogue for hyperbolic curves of the theory of isogenies and Tate modules of abelian varieties that plays a central role in [Falt1].
- (6^{flt}) The important role played by **polarizations** of **abelian varieties** in [Falt1] may be compared to the quite *central role* played by *commutators* of *theta groups* in the theory of *rigidity properties* of *mono-theta environments*, and hence in inter-universal Teichmüller theory as a whole [cf. the discussion of §3.4, (iv); §3.8, (9^{gau}); §4.1, (ii), (5^{cls})].
- (7^{flt}) The **logarithmic geometry** of **toroidal compactifications**, which plays an important role in [Falt1], may be compared to the *logarithmic geometry* of special fibers of stable curves. The latter instance of logarithmic geometry is the starting point for the *combinatorial anabelian geometry* of tempered fundamental groups developed in [Semi], which plays an important role throughout inter-universal Teichmüller theory.
- (ii) <u>Arithmetic holomorphicity versus mono-analyticity/multiradial-ity:</u> One way to summarize the discussion of (i), as well as a substantial portion of the discussion of §4.2 [cf. [IUTchIV], Remark 2.3.3, (iii)], is as follows:

inter-universal Teichmüller theory may be understood, to a substan-

tial extent, as a sort of hyperbolic, mono-analytic/multiradial analogue of the the abelian, arithmetic holomorphic theory of [Falt1].

Indeed, this is precisely the point of view of the discussion of §4.2, (iii), concerning the relationship between the essentially arithmetic holomorphic nature of **global** class field theory and the essentially mono-analytic nature of **Kummer theory**. If one takes the point of view [cf. the discussion of §2.3, §2.4, §2.5, §2.6; Examples 2.14.2, 2.14.3] that Galois or arithmetic fundamental groups should be thought of as "arithmetic tangent bundles", then the point of view of the present discussion may be formulated in the following way [cf. the discussion of the final portion of [IUTchI], §I2]: Many results in the **conventional** framework of arithmetic geometry that concern Galois or arithmetic fundamental groups may be understood as results to the effect that some sort of

" H^0 (arithmetic tangent bundle)"

does indeed coincide with some sort of very small collection of scheme-theoretic—i.e., arithmetic holomorphic—auto-/endo-morphisms. Indeed, examples of this sort of phenomenon include

- (1^{hol}) the version of the **Tate Conjecture** proven in [Falt1];
- (2^{hol}) various **bi-anabelian** results [cf. the discussion of §2.7, (v)] i.e., fully faithfulness results in the style of various versions of the "Grothendieck Conjecture" in anabelian geometry;
- (3^{hol}) the "tiny" special case of the theory of [Falt1] discussed in §2.3 to the effect that "Frobenius endomorphisms of NF's" of the desired type [i.e., that yield bounds on heights cf. the discussion of §2.4!] cannot exist, i.e., so long as one restricts oneself to working within the framework of conventional scheme theory;
- (4^{hol}) the results of [Wiles] concerning *Galois representations* [cf. the discussion of [IUTchI], §I5], which may be summarized as asserting, in essence, that, roughly speaking, **nontrivial deformations** of **Galois representations** that satisfy suitable natural conditions **do not exist**.

All of the results just stated assert some sort of

"arithmetic holomorphic nonexistence"

[up to a very small number of exceptions], hence lie in a fundamentally different direction from the content of **inter-universal Teichmüller theory**, which, in effect, concerns the construction — or

"non-arithmetic holomorphic existence"

— of a "Frobenius endomorphism of an NF", by working *outside* the framework of *conventional scheme theory*, i.e., by considering suitable mono-analytic/multiradial deformations of the arithmetic holomorphic structure, that is to say, at the level of suggestive notation, by considering

" H^1 (arithmetic tangent bundle)".

(iii) <u>Comparison with the metric proofs of Parshin and Bogomolov</u> <u>in the complex case</u>: Parshin [cf. [Par]] and Bogomolov [cf. [ABKP], [Zh]] have given proofs of *geometric versions* over the complex numbers of the Mordell and Szpiro Conjectures, respectively [cf. the discussion of [IUTchIV], Remarks

- 2.3.4, 2.3.5]. Parshin's proof of the geometric version of the Mordell Conjecture is discussed in detail in [IUTchIV], Remark 2.3.5, while Bogomolov's proof of the geometric version of the Szpiro Conjecture is discussed in detail in [BogIUT]. The relationships of these two proofs to *one another*, as well as to the *arithmetic theory*, may be summarized as follows:
- (1^{PB}) Both proofs revolve around the consideration of **metric estimates** of the **displacements** that arise from various *natural actions* of elements of the [usual topological] **fundamental groups** that appear [cf. the discussion at the beginning of [IUTchIV], Remark 2.3.5].
- (2^{PB}) Both Parshin's and Bogomolov's proofs concern the metric geometry of the complex spaces that appear. On the other hand, these two proofs differ fundamentally in that whereas the metric geometry that appears in Parshin's proof concerns the holomorphic geometry that arises from the Kobayashi distance i.e., in effect, the Schwarz lemma of elementary complex analysis the metric geometry that appears in Bogomolov's proof concerns the real analytic hyperbolic geometry of the upper half-plane [cf. [IUTchIV], Remark 2.3.5, (PB1)].
- (3^{PB}) The difference observed in (2^{PB}) is interesting in that in corresponds precisely to the difference discussed in (ii) above between the proof of the arithmetic Mordell Conjecture [for NF's!] in [Falt1] and interuniversal Teichmüller theory [cf. the discussion of [IUTchIV], Remark 2.3.5, (i)].
- (4^{PB}) Parshin's proof concerns, as one might expect from the statement of the Mordell Conjecture, rough, qualitative estimates. This state of affairs contrasts sharply, again as one might expect from the statement of the Szpiro Conjecture, with Bogomolov's proof, which concerns effective, quantitative estimates [cf. the discussion of [IUTchIV], Remark 2.3.5, (ii)].
- (5^{PB}) The appearance of the *Kobayashi distance* i.e., in essence, the *Schwarz lemma* of elementary complex analysis in (2^{PB}) is of interest in light of the point of view discussed in §3.3, (vi); §3.7, (iv), concerning the correspondence between the use of **Belyi maps** in inter-universal Teichmüller theory, i.e., in the context of **Belyi cuspidalizations** or **height estimates**, as a sort of means of **arithmetic analytic continuation**, and the classical complex theory surrounding the **Schwarz lemma** [cf. the discussion of [IUTchIV], Remark 2.3.5, (iii)].

§4.4. Atavistic resemblance in the development of mathematics:

(i) Questioning strictly linear models of evolution: Progress in mathematics is often portrayed as a strictly linear affair — a process in which old theories or ideas are rendered essentially obsolete, and hence forgotten, as soon as the essential content of those theories or ideas is "suitably extracted/absorbed" and formulated in a more "modern form", which then becomes known as the "state of the art". The historical development of mathematics is then envisioned as a sort of towering edifice that is subject to a perpetual appending of higher and higher floors, as new "states of the art" are discovered. On the other hand, it is often overlooked that there is in fact no intrinsic justification for this sort of strictly linear model of evolution. Put another way, there is

no rigorous justification for excluding the possibility that a particular approach to mathematical research that happens to be embraced without doubt by a particular community of mathematicians as the path forward in this sort of strictly linear evolutionary model may in fact be nothing more than a dramatic "wrong turn", i.e., a sort of unproductive march into a meaningless cul de sac.

Indeed, Grothendieck's original idea that **anabelian geometry** could shed light on **diophantine geometry** [cf. the discussion at the beginning of [IUTchI], §I5] suggests precisely this sort of skepticism concerning the "linear evolutionary model" that arose in the 1960's to the effect that progress in arithmetic geometry was best understood as a sort of

strictly linear march toward the goal of realizing the theory of motives, i.e., a sort of idealized version of the notion of a Weil cohomology.

In more recent years, another major "linear evolutionary model" that has arisen, partly as a result of the influence of the work of Wiles [cf. [Wiles]] concerning **Galois** representations, asserts that progress in arithmetic geometry is best understood as a sort of

strictly linear march toward the goal of realizing the representationtheoretic approach to arithmetic geometry constituted by the Langlands program.

As discussed in §4.3, (ii); [IUTchI], §I5,

 (a^{app}) the "mono-anabelian" approach to arithmetic geometry constituted by inter-universal Teichmüller theory

differs fundamentally not only from

 (b^{app}) the motive-/cohomology-theoretic and representation-theoretic approaches to arithmetic geometry just discussed — both of which may be characterized as "abelian"! —

but also from

 (c^{app}) the "bi-anabelian" approach involving the section conjecture that was apparently originally envisioned by Grothendieck.

Here, we recall, moreover, the point of view of the *dichotomy* discussed in §4.3, (ii), concerning **arithmetic holomorphicity** and **mono-analyticity/multiradiality**, i.e., to the effect that the *difference* between (a^{app}) , on the one hand, and *both* (b^{app}) and (c^{app}) , on the other, may be understood [if, for the sake of brevity, one applies the term "holomorphic" as an abbreviation of the term "arithmetically holomorphic"] as the difference between

non-holomorphic existence and holomorphic nonexistence.

Another way to understand, at a very rough level, the difference between (a^{app}) and (b^{app}) is as a reflection of the deep structural differences between

[discrete or profinite] **free groups** and **matrix groups** [with discrete or profinite coefficients]

— cf. the discussion of [IUTchI], §I5. Finally, at a much more elementary level, we note that the theory of **Galois groups** — which may be thought of as a mechanism that allows one to pass from field theory to group theory — plays a fundamental role in (a^{app}) , (b^{app}) , and (c^{app}) . From this point of view, the difference between (a^{app}) , on the one hand, and (b^{app}) [and, to a slightly lesser extent, (c^{app})], on the other, may be understood as the difference between the "inequalities"

group theory ≫ field theory and field theory ≫ group theory

- i.e., the issue of whether one regards [abstract] group theory as the central object of interest, while field theory [which we understand as including vector spaces over fields, hence also representation theory] is relegated to playing only a subordinate role, or vice versa.
- (ii) Examples of atavistic development: An alternative point of view to the sort of strictly linear evolutionary model discussed in (i) is the point of view that progress in mathematics is best understood as a much more complicated family tree, i.e., not as a tree that consists solely of a single trunk without branches that continues to grow upward in a strictly linear manner, but rather as

a much more complicated **organism**, whose growth is sustained by an intricate mechanism of interaction among a vast multitude of branches, some of which sprout not from branches of relatively recent vintage, but rather from **much older**, **more ancestral branches** of the organism that were entirely irrelevant to the recent growth of the organism.

In the context of the present paper, it is of interest to note that this point of view, i.e., of

substantially different multiple evolutionary branches that sprout from a *single common ancestral branch*, is reminiscent of the notion of "mutually alien copies", which forms a *central theme* of the present paper [cf. the discussion of §2.7, (i), (ii); §3.8].

Phenomena that support this point of view of an "atavistic model of mathematical development" may be seen in many of the examples discussed in §4.1, §4.2, and §4.3 such as the following:

- (1^{atv}) The very elementary construction of **Belyi maps** in the early 1980's, or indeed **noncritical Belyi maps** in [NCBelyi], could easily have been discovered in the late nineteenth century [cf. §4.3, (ii), (5^{flt}); §4.3, (iii), (5^{PB})].
- (2^{atv}) The application of Belyi maps to **Belyi cuspidalization** [cf. [AbsTopII], §3] could easily have been discovered in the mid-1990's [cf. also (1^{atv})].
- (3^{atv}) The application of noncritical Belyi maps to **height estimates** in [GenEll], §2, could easily have been discovered in the mid-1980's [cf. also (1^{atv})].
- (4^{atv}) The **Galois-theoretic** interpretation of the **Gaussian integral** or **Jacobi's identity** furnished by inter-universal Teichmüller theory [cf. the discussion of §3.8; the discussion at the end of §3.9, (iii); the discussion of the final portion of §4.1, (i)] could easily have been discovered much earlier

- than in the series of papers [IUTchI], [IUTchII], [IUTchIII], [IUTchIV].
- (5^{atv}) The interpretation of **changes of universe** in the context of **non-ring-theoretic** "arithmetic changes of coordinates" as in the discussion of §2.10 is entirely elementary and could easily have been discovered in the 1960's [cf. §4.1, (ii), (1^{cls}), (2^{cls})].
- (6^{atv}) The use of **Hodge-Tate representations** as in $[\mathbb{Q}_pGC]$ or [AbsTopI], §3, could easily have been discovered in the 1960's [cf. §4.1, (ii), (3^{cls})].
- (7^{atv}) The use of **Hodge-Tate decompositions** as in [pGC] could easily have been discovered in the 1980's [cf. §4.1, (ii), (4^{cls})].
- (8^{atv}) The **anabelian** approach to **theta functions** on **Tate curves** taken in [EtTh] [cf. §3.4, (iii), (iv)] could easily have been discovered in the mid-1990's [cf. §4.1, (ii), (5^{cls})].
- (9^{atv}) The **non-representation-theoretic** use of the structure of **theta groups** in the theory of [EtTh] [cf. the discussion at the end of §3.4, (iv)] could easily have been discovered in the 1980's [cf. §4.1, (ii), (5^{cls}), (6^{cls})].
- (10^{atv}) **Scheme-theoretic Hodge-Arakelov theory**, which may be regarded as a *natural extension* of the [the portion concerning *elliptic curves* of] *Mumford's* theory of **algebraic theta functions**, could easily have been discovered in the late 1960's [cf. §4.1, (ii), (6^{cls})].
- (11^{atv}) The technique of **mono-anabelian transport** in the context of *positive* characteristic anabelian geometry, i.e., in the style of Example 2.6.1, could easily have been discovered in the 1980's [cf. §4.1, (ii), (7^{cls})].
- (12^{atv}) The use of **monoids** as in the theory of **Frobenioids** could easily have been discovered in the mid-1990's [cf. §4.1, (ii), (8^{cls})].
- (13^{atv}) The notion of **multiradiality** is *entirely elementary* and could easily have been discovered in the late 1960's [cf. §4.1, (ii), (9^{cls})].
- (14^{atv}) The point of view of taking a **Kummer-theoretic** approach to **Kronecker's Jugendtraum**, i.e., as discussed in §4.2, (ii), could easily have been discovered much earlier than in the series of papers [IUTchI], [IUTchII], [IUTchIII], [IUTchIV].

In this context, we note that the atavistic model of mathematical development just discussed also suggests the possibility that the theory of **Frobenioids** — which, as was discussed in §3.5, was originally developed for reasons that were [related to, but, strictly speaking] independent of inter-universal Teichmüller theory, and is, in fact, only used in inter-universal Teichmüller theory in a relatively weak sense — may give rise, at some distant future date, to further developments of interest that are not directly related to inter-universal Teichmüller theory.

(iii) Escaping from the cage of deterministic models of mathematical development: The adoption of strictly linear evolutionary models of progress in mathematics of the sort discussed in (i) tends to be highly attractive to many mathematicians in light of the intoxicating simplicity of such strictly linear evolutionary models, by comparison to the more complicated point of view discussed in (ii). This intoxicating simplicity also makes such strictly linear evolutionary models—together with strictly linear numerical evaluation devices such as the "number of papers published", the "number of citations of published papers", or other likeminded narrowly defined data formats that have been concocted for measuring progress in mathematics—highly enticing to administrators who are charged with the tasks of evaluating, hiring, or promoting mathematicians. Moreover, this

state of affairs that regulates the collection of individuals who are granted the license and resources necessary to actively engage in mathematical research tends to have the effect, over the long term, of **stifling efforts** by young researchers to conduct **long-term mathematical research** in directions that **substantially diverge** from the **strictly linear evolutionary models** that have been adopted, thus making it exceedingly difficult for *new* "unanticipated" *evolutionary branches* in the development of mathematics to sprout. Put another way,

inappropriately narrowly defined strictly linear evolutionary models of progress in mathematics exhibit a strong and unfortunate tendency in the profession of mathematics as it is currently practiced to become something of a self-fulfilling prophecy — a "prophecy" that is often zealously rationalized by dubious bouts of circular reasoning.

In particular, the issue of

escaping from the cage of such narrowly defined deterministic models of mathematical development stands out as an issue of crucial strategic importance from the point of view of charting a sound, sustainable course in the future development of the field of mathematics, i.e., a course that cherishes the priviledge to foster genuinely novel and unforeseen evolutionary branches in its development.
