On generating functions for certain sums of multiple zeta values and a formula of S. Zlobin

By

NORIKO WAKABAYASHI*

Abstract

Generating functions for certain sums of multiple zeta-star values are discussed and an alternative proof of a formula of S. Zlobin is given.

§1. Generating functions for certain sums of multiple zeta values

The multiple zeta values are real numbers first considered in Euler [5]. These numbers have been appeared in various fields in mathematics and physics. There are many linear relations among these values with rational coefficients. One of the main problems in this area is to clarify the all relations among multiple zeta values.

The multiple zeta values are natural generalization of Riemann zeta values. There are two types of definition for multiple zeta values. For a multi-index \( k = (k_1, k_2, \ldots, k_n) \) \( (k_i \in \mathbb{N}, k_1 \geq 2) \), the multiple zeta values are defined by

\[
\zeta(k) = \zeta(k_1, k_2, \ldots, k_n) = \sum_{m_1 > m_2 > \ldots > m_n > 0} \frac{1}{m_1^{k_1} m_2^{k_2} \cdots m_n^{k_n}}
\]

and

\[
\zeta^*(k) = \zeta^*(k_1, k_2, \ldots, k_n) = \sum_{m_1 \geq m_2 \geq \ldots \geq m_n \geq 1} \frac{1}{m_1^{k_1} m_2^{k_2} \cdots m_n^{k_n}}.
\]

The former is normally called a multiple zeta value and used mainly in the mathematical literatures in last two decades and the latter is called multiple zeta-star value (MZV and MZSV, respectively, for short). There exist natural \( \mathbb{Q} \)-linear relations between MZVs and MZSVs. Any MZSV can be expressed as a linear combination of MZVs and vice versa. Therefore two \( \mathbb{Q} \)-vector spaces generated by both values coincide with each other. On the other hand, there are many \( \mathbb{Q} \)-linear relations that hold among multiple zeta values. Some part of these relations can be described clearly by using MZSVs.

For any multi-index \( \mathbf{k} = (k_1, k_2, \ldots, k_n) \) \( (k_i \in \mathbb{N}) \), the weight, depth and \( i \)-height of \( \mathbf{k} \) are by definition the integers \( \text{wt}(\mathbf{k}) = k_1 + k_2 + \cdots + k_n = k \), \( \text{dep}(\mathbf{k}) = n \) and \( \text{i-ht}(\mathbf{k}) = \# \{ l | k_l \geq i + 1 \} \), respectively. The generalized height \( \text{i-ht} \) is defined in Li [6]. If \( i = 1 \), it is introduced by Ohno-Zagier [7] and usually called (1-)height. An index \( \mathbf{k} = (k_1, k_2, \ldots, k_n) \) is called admissible, if \( k_1 \geq 2 \).

Let \( r \) be a positive integer. For any integers \( k, n, h_1, h_2, \ldots, h_r \) \( (k, n, h_i \geq 0) \), we set

\[
I(k, n, h_1, h_2, \ldots, h_r) = \{ \mathbf{k} \mid \text{wt}(\mathbf{k}) = k, \text{dep}(\mathbf{k}) = n, \text{1-ht}(\mathbf{k}) = h_1, \ldots, \text{r-ht}(\mathbf{k}) = h_r \}
\]

\[
I_j(k, n, h_1, h_2, \ldots, h_r) = \{ \mathbf{k} = (k_1, k_2, \ldots, k_n) \mid \mathbf{k} \in I(k, n, h_1, h_2, \ldots, h_r), k_1 \geq j + 2 \},
\]

where \( j = 0, 1, 2, \ldots, r - 1 \).

Ohno-Zagier [7] gives a concrete expression of the generating function for sums of multiple zeta values of fixed weight, depth and 1-height;

\[
\sum_{k,n,h_1 \geq 0} \left( \sum_{\mathbf{k} \in I_0(k,n,h_1)} \zeta(\mathbf{k}) \right) x^{k-n-h_1} y^{n-h_1} z^{h_1-1} = \frac{1}{xy-z} \left\{ 1 - \exp \left( \sum_{n=2}^{\infty} \frac{\zeta(n)}{n} (x^n + y^n - a_1^n - a_2^n) \right) \right\} = \frac{1}{xy-z} \left( 1 - 2 F_1 \left( \begin{array}{lll} a_1 - x, a_2 - x & \mathbb{R} \; \mathrm{F} 1 \end{array} \right) \right),
\]

where \( a_1 \) and \( a_2 \) are defined by \( a_1 + a_2 = x + y \) and \( a_1 a_2 = z \), \( 2 F_1 \left( \begin{array}{lll} a, b & \mathbb{R} \; \mathrm{F} 1 \end{array} \right) \) denotes the Gauss hypergeometric function \( 2 F_1 \left( \begin{array}{lll} a, b & \mathbb{R} \; \mathrm{F} 1 \end{array} \right) = \sum_{n=0}^{\infty} \frac{(a)_n(b)_n t^n}{(c)_n n!} \), and \( (a)_n \) means the Pochhammer symbol \( (a)_n = a(a + 1)(a + 2) \cdots (a + n - 1) \). In particular, all of the coefficients of left-hand side of the above generating function can be expressed as polynomials in Riemann zeta values \( \zeta(2), \zeta(3), \ldots \) with rational coefficients.

On the other hand, Aoki-Kombu-Ohno [1] (see also [2]) considers a counterpart of the result of Ohno-Zagier for multiple zeta-star values and obtains the following
expression of generating function:

\[
\sum_{k,n,h_{1}\geq 0} \left( \sum_{k \in I_{0}(k,n,h_{1})} \zeta^{*}(k) \right) x^{k-n-h_{1}} y^{n-h_{1}} z^{2h_{1}+2} = \frac{1}{(1-x)(1-y)-z^{2}} {}_{3}F_{2} \left( \frac{1-x,1,1}{b_{1}+2,b_{2}+2};1 \right),
\]

where \( b_{1} \) and \( b_{2} \) are defined by \( b_{1} + b_{2} = -(x+y) \) and \( b_{1}b_{2} = -(z^{2} - xy) \), and \( {}_{r+1}F_{r} \left( \frac{a_{1},a_{2},\ldots,a_{r+1}}{b_{1},b_{2},\ldots,b_{r}};t \right) \) denotes the generalized hypergeometric function

\[
{}_{r+1}F_{r} \left( \frac{a_{1},a_{2},\ldots,a_{r+1}}{b_{1},b_{2},\ldots,b_{r}};t \right) = \sum_{n=0}^{\infty} \frac{(a_{1})_{n}(a_{2})_{n}\cdots(a_{r+1})_{n}}{(b_{1})_{n}(b_{2})_{n}\ldots(b_{r})_{n}} \frac{t^{n}}{n!}
\]

for any positive integer \( r \).

Li [6] generalizes the generating function of Ohno-Zagier and gives an expression of it in terms of generalized hypergeometric functions \( {}_{r+1}F_{r} \left( \frac{a_{1},a_{2},\ldots,a_{r+1}}{b_{1},b_{2},\ldots,b_{r}};t \right) \).

In this paper, we consider generating functions of multiple zeta values of fixed weight, depth and \( i \)-heights and introduce expressions of them by using generalized hypergeometric functions. This part is an announcement of the author’s joint work [3] with Aoki and Ohno. Moreover we give an alternative proof of a formula of Zlobin by specializing the expression.

We define a sum \( X_{0} \) for any integers \( k, n, h_{1}, h_{2}, \ldots, h_{r} \ (k,n,h_{i} \geq 0) \), and its generating function \( \Phi_{0}^{*} \) as follows:

\[
X_{0}(k,n,h_{1},h_{2},\ldots,h_{r}) = \sum_{k \in I_{0}(k,n,h_{1},h_{2},\ldots,h_{r})} \zeta^{*}(k),
\]

\[
\Phi_{0}^{*} = \Phi_{0}^{*}(x_{1},x_{2},\ldots,x_{r+2}) = \sum_{k \geq n + \sum_{i=1}^{r} h_{i}} \times x_{1}^{k-n-\sum_{i=1}^{r} h_{i}} x_{2}^{n-h_{1}} x_{3}^{h_{1}-h_{2}} \cdots x_{r+1}^{h_{r}-1-h_{r}} x_{r+2}^{h_{r}}.
\]

In the above definitions, the sum is treated as 0 whenever the index set is empty. Our main result of [3] will then be
Theorem 1.1. Let $r$ be a positive integer. Then we obtain

$\Phi_0^* = \left\{1 + (x_1 + x_2) - \sum_{q=0}^{r-1} (x_{r+2-q} - x_1x_{r+1-q})\right\}^{-1}$

$\times \sum_{m=0}^{r-1} A_m \left(\frac{d}{dt}\right)^m t_{r+2-1} \left. F_{r+1} \left(1 - x_1, 1, \ldots, 1 \right) \left(b_1 + 2, b_2 + 2, \ldots, b_{r+1} + 2, t\right)\right|_{t=1},$

where $b_i$ ($i = 1, \ldots, r + 1$) are defined by

$\left\{\begin{array}{l}
b_1 + b_2 + \cdots + b_{r+1} = -(x_1 + x_2), \\
\sum_{1 \leq i_1 < i_2 < \ldots < i_j \leq r+1} b_{i_1}b_{i_2}\cdots b_{i_j} = -(x_{j+1} - x_1x_j), j = 2, 3, \ldots, r+1,
\end{array}\right.$

$A_m$ is expressed by using the Stirling numbers of the second kind as

$A_m = \sum_{j=m}^{r-1} (x_{r+2-j} - x_1x_{r+1-j}) \left\{\begin{array}{l}
j \\
m\end{array}\right\} + x_1x_2 \left\{\begin{array}{l}
r - 1 \\
m\end{array}\right\},$

and the Stirling number of the second kind $\left\{\begin{array}{l}
n \\
m\end{array}\right\}$ is the number of ways of partitioning a set of $n$ elements into $m$ non-empty subsets.

§ 2. A formula of S. Zlobin

In some special cases, we can explicitly evaluate $\Phi_0^*$ by using Theorem 1.1. For example, we get one of the results of Zlobin [9]. By setting $r = l - 1$, $x_1 = x_2 = \cdots = x_l = 0$, $x_{l+1} = x$, we have

$\left\{\begin{array}{l}
\text{wt}(k) = ln, \\
\text{dep}(k) = n, \\
1-\text{ht}(k) = 2-\text{ht}(k) = \cdots = (l-1)-\text{ht}(k) = n, \\
l-\text{ht}(k) = \cdots = 0.
\end{array}\right.$

From the definition of $\Phi_0^*$, we have

$\Phi_0^* = \sum_{n=1}^{\infty} X_0(ln, n, n, \ldots, n) x^n$

$= \sum_{n=1}^{\infty} \zeta^*(l, l, \ldots, l) x^n.$
On the other hand, substituting \( l - 1 \) for \( r \) of Theorem 1.1 \((x_1 = x_2 = \cdots = x_l = 0, \ x_{l+1} = x)\), we get the following:

\[
\Phi_0^* = \frac{x}{1-x} t^t \left[ \Phi_0^* \right]_{t=1} = \frac{x}{1-x} \sum_{m=0}^{\infty} \frac{(m!)^{l+.1}}{(b_1+2)_m (b_2+2)_m \cdots (b_l+2)_m m!}
\]

\[(2.1)\]

where \( b_i \) \((i = 1, \ldots, l)\) are defined by

\[
\begin{cases}
    b_1 + b_2 + \cdots + b_l = 0, \\
    \sum_{1 \leq i_1 < i_2 < \cdots < i_j \leq l} b_{i_1} b_{i_2} \cdots b_{i_j} = 0, \ j = 2, 3, \ldots, l-1, \\
    b_1 b_2 \cdots b_l = -x.
\end{cases}
\]

Putting \( f(z) = (z+b_1)(z+b_2)(z+b_3)\cdots (z+b_l) = z^l - x \), we obtain

\[
(b_1 + 2)_m (b_2 + 2)_m \cdots (b_l + 2)_m = \prod_{i=1}^{l} \prod_{j=2}^{m+1} (b_i + j).
\]

Interchanging two products, we have

\[
\prod_{j=2}^{m+1} \prod_{i=1}^{l} (b_i + j) = \prod_{j=2}^{m+1} f(j) = (2^l - x)(3^l - x) \cdots ((m+1)^l - x).
\]

Applying the above relation to the denominator of (2.1), we get

\[
\Phi_0^* = \frac{x}{1-x} \sum_{m=0}^{\infty} \frac{(m!)^l}{(2^l - x)(3^l - x) \cdots ((m+1)^l - x)}
\]

Multiplying \((m+1)^l\) to the numerator and the denominator, the above equality becomes

\[
\sum_{m=0}^{\infty} \left( \prod_{j=1}^{m+1} \frac{j^l}{j^l - x} \right) \frac{x}{(m+1)^l} = \sum_{m=0}^{\infty} \left( \prod_{j=1}^{m+1} \frac{1 - \frac{x}{j^l}}{j^l} \right) \frac{x}{(m+1)^l}
\]

\[(2.3)\]
To complete our computation, we need the following formula obtained by Euler [4]:

\[
1 + \sum_{m=1}^{\infty} \frac{a_m}{(1-a_1)(1-a_2)\cdots(1-a_m)} = \prod_{m=1}^{\infty} (1-a_m)^{-1},
\]

where we assume that \(\sum |a_m|\) is convergent.

The following equation is immediately obtained when we apply (2.4) to equation (2.3).

\[
\Phi_0^* = \prod_{j=1}^{\infty} \left(1 - \frac{x}{j^l}\right)^{-1} - 1.
\]

Thus we obtain

\[
1 + \sum_{n=1}^{\infty} \zeta^*({\underbrace{1, 1, \ldots, 1}_n}) x^n = \prod_{j=1}^{\infty} \left(1 - \frac{x}{j^l}\right)^{-1}.
\]

Zlobin [9] (see also Vasil’ev [8]) obtains (2.5) in the course of the proof of his formula;

\[
\zeta^*({\underbrace{1, \{1\}_{l-2}}_n}, 1) = l\zeta(lm + 1),
\]

where we denote \((k, \ldots, k)\) by \(\{k\}_n\). Therefore our specialization of Theorem 1.1 provides another proof of (2.5).
