The Boundary Layer Equation
\[ x''' + 2xx'' + 2\lambda(1-x^2) = 0 \]

Keio Univ. K. Hayashi

In the theory of viscous fluids the following non-linear boundary value problem for a function \( x(t) \) of a real variable \( t \geq 0 \) involving a constant \( \lambda \) plays an important part:

1. \[ x''' + 2xx'' + 2\lambda(1-x^2) = 0 \]
2. \( x(0) = x'(0) = 0, \quad x'(\infty) = 1 \)
3. \( 0 < x'(t) < 1 \) for \( 0 < t < \infty \).

For \( \lambda \geq 0 \) H. Weyl (1942) first proved that there exists a continuous solution of the problem.

For \( \lambda < 0 \) (|\( \lambda \)| small) S.P. Hastings (1971) first showed the existence of solutions as far as we know.

On the other hand, it is known that the separation phenomenon of boundary layer occurs for \( \lambda = -0.1988.. \), and M. Iwano (1974) tried to show the existence of solutions for negative \( \lambda \) as small as possible.

In this report we shall extend the value of such \( \lambda \) as closely as possible to the value \(-0.1988..\).

Our method of proof, which is close to that of W.A. Coppel (1960), owes to Kneser's property, which was shown by M. Hukuhara (1967). Although we can solve this problem by using the continuity dependence property of
solutions to initial data, because the equation (1) has the property that the solution for an initial value problem is unique, our proof was found by examining the paper of M. Hukuhara (1967).

1. An Existence Theorem of Solutions

Theorem 1. If $\lambda > -1/6$, then the equation (1) has a continuous solution satisfying (2), (3).

We choose $x$ as a new independent variable and $y = x^{1/2}$ as a new dependent variable. The equation (1) is transformed into

(4) \[ \ddot{y} = -\frac{1}{y} (2xy + 4\lambda(1-y)) = f(x, y, \dot{y}) \]

the boundary condition (2) into

(5) \[ y(0) = 0, \quad y(\infty) = 1 \]

and the condition (3) into

(6) \[ 0 < y(x) < 1 \quad \text{for} \quad 0 < x < \infty. \]

Consequently, Theorem 1 replaced by the following

Theorem 1'. If $\lambda > -1/6$, then (4) has a continuous solution satisfying (5), (6).

To prove the Theorem, we construct three functions

$\Omega(x, y), \overline{\Omega}(x, y), \omega(x)$.

Here $y = \omega(x)$ is a continuous function for $0 \leq x < \infty$, satisfying the conditions: $\omega(0) = 0, \quad 0 < \omega(x) < 1 \quad \text{for} \quad 0 < x < \infty$. And $\overline{\Omega}(x, y), \underline{\Omega}(x, y)$ are continuous functions for $0 < x < \infty$, $\omega(x) \leq y < 1$, with $\underline{\Omega}(x, 1) = 0, \quad 0 < \underline{\Omega}(x, y) < \overline{\Omega}(x, y)$. 
Using these three functions, we define a compact subset $D$ in the $(x,y,z)$-space as follows:

$$D : \alpha \leq x \leq K \quad \omega(x) \leq y \leq 1 \quad \underline{O}(x,y) \leq z \leq \overline{O}(x,y)$$

We divide the boundary $\partial D$ into seven parts $S_0$, $S_1$, ..., $S_6$.

$S_0$ is a segment: $\alpha \leq x < K$, $y = 0$, $z = 1$.

We remark this segment is itself a solution curve of (4).

$S_1 : x = \alpha$, $\omega(x) < y < 1$, $\underline{O}(x,y) < z < \overline{O}(x,y)$

$S_2 : x = K$, ...

Since the $x$-component of the velocity vector is 1, any point of $S_1$ is a strictly ingress point and any point of $S_2$ is a strictly egress point.

We call a point $(\bar{x}, \bar{y}, \bar{z})$ in $\partial D$ an egress point if the solution curve $(x,y(x),z(x))$ passing through $(\bar{x}, \bar{y}, \bar{z})$ is in the interior of $D$ for $\bar{x} - \epsilon \leq x < \bar{x}$ for some positive $\epsilon$, if in addition there is a small $\epsilon > 0$ such that for $\bar{x} < x \leq \bar{x} + \epsilon$ the solution curve $(x,y(x),z(x))$ is not in $D$, the point is called a strictly egress point. The ingress point and strictly ingress point are similarly defined.

And we define

$S_3 : \alpha \leq x < K$, $y = 1$, $\underline{O}(x,y) < z \leq \overline{O}(x,y)$.

It is easily verified that any point of $S_3$ is a strictly egress point.
$S_4: \alpha \leq x < K, \omega(x) \leq y < l, \ z = \Omega(x, y),$  
$S_5: \alpha \leq x < K, \ y = \omega(x), \ \Omega(x, y) < z < \Omega_0(x, y),$  
$S_6: \alpha \leq x < K, \ \omega(x) \leq y < l, \ z = \Omega(x, y).$  

The boundary $\partial D = S_0 + S_1 + \ldots + S_6.$

Now we impose $S_4, S_5, S_6$ the following conditions

(E) Any point of $S_4$ is a strictly egress point,
(I) Any point of $S_5, S_6$ is a strictly ingress point.

Then any point of $\partial D$ is a strictly egress point or a strictly ingress point or in $S_0$ which is a solution curve contained in $\partial D$.

We consider solutions starting from a point of a segment

$L: \ x = \alpha, \ y = \omega(\alpha), \ \Omega(x, y) \leq z < \Omega(x, y)$

contained in $\partial D$. And we define a map $p : L \to \partial D$ as follows;

for $(\bar{x}, \bar{y}, \bar{z})$ in $L$, $p(\bar{x}, \bar{y}, \bar{z})$ is the first point $(x, y, z)$, $x \geq \bar{x}$ where the solution starting from $(\bar{x}, \bar{y}, \bar{z})$ meets $\partial D_\varepsilon$, the set of all egress points.

By the uniqueness property for an initial value problem, the solution curve starting from a point in $L$ cannot meet the set $S_0$. In this case $\partial D_\varepsilon = S_1 + S_3 + S_4$, and any egress point is a strictly egress point. Hence it is easy to prove that the map $p : L \to \partial D_\varepsilon$ is continuous. If this condition is not satisfied, that is, there is a point which is an egress point but not a strictly egress point, then the map $p$ is not always continuous.
Since \( L \) is a connected set, \( p(L) \) is also a connected set contained in \( S_2 + S_3 + S_4 \). For the lowest point \( P_0 \) in \( L \), \( p(P_0) = P_0 \) because \( P_0 \) in \( S_4 \) is an egress point. And if we construct these walls appropriately it is easily calculated that the solution starting from the highest point \( P_1 \) in \( L \) meets \( S_3 \) first. That is, \( p(P_1) \in S_3 \).

Consequently \( p(L) \), which is contained in \( S_2 + S_3 + S_4 \), intersects \( S_3 \) and \( S_4 \). \( p(L) \) is a connected set but \( S_3 + S_4 \) is not connected, hence \( p(L) \) intersects \( S_2 \). That is, \( p^{-1}(S_2) \) is a nonempty compact subset of \( L \).

And we obtain a solution \( y(x) \) of (4) for \( \alpha \leq x \leq K \), with
\[
y(\alpha) = \omega(\alpha) \quad \text{and} \quad \Omega(\alpha, \omega(\alpha)) \leq \dot{y}(\alpha) \quad \text{for} \quad \alpha < x < K.
\]

If \( K < K' \), a solution starting from a point of \( L \) reach to the set \( S_2^{K'} \) corresponding to \( K' \) must pass through the set \( S_2^K \) corresponding to \( K \). Therefore \( p^{-1}(S_2^{K'}) \subseteq p^{-1}(S_2^K) \). Since these sets are compact, there exists at least one point \( P \)
\[
P \in \bigcap_{K \text{ large}} p^{-1}(S_2^K)
\]
And we obtain a solution \( y(x) \) of (4) for \( \alpha \leq x < \infty \).

In this case \( y(\alpha) > 0 \), \( \dot{y}(\alpha) > 0 \). But this equation has a sort of monotone property as follows (P. Hartman(1964)).

If for the initial condition \( y(\alpha) = \beta \), \( \dot{y}(\alpha) = \gamma \geq 0 \), there is a solution of (4) satisfying (5), (6), then for the initial condition \( 0 \leq y(\alpha) \leq \beta \), \( 0 \leq \dot{y}(\alpha) \leq \gamma \), there is a solution of (4) satisfying (5), (6).
In particular there is a solution of (4) with initial conditions
\[ y(\alpha) = 0, \quad \dot{y}(\alpha) = 0 \quad \text{for any } \alpha > 0 \text{ small}. \]

Using the continuity dependence property for the initial data, we obtain a solution \( y(x) \) with initial conditions
\[ y(0) = 0, \quad \dot{y}(0) = 0 \]
for \( 0 \leq x < \infty \).

This is the desired solution.

It is remained to construct three functions \( \overline{\Omega}(x,y), \underline{\Omega}(x,y), \omega(x) \) satisfying the conditions (E) and (I).

As sufficient conditions for these conditions, we have following

(E') \[ \overline{\Omega}(x,y) + \overline{\Omega}(y,x) \Omega(y) > f(x,y, \Omega(y)) \quad \text{for } 0 < x < \infty, \quad \omega(x) \leq y < 1 \]

(I') \[ \Omega(x,\omega(x)) > \omega(x) \]
\[ \overline{\Omega}(x,y) + \overline{\Omega}(y,x) \Omega(y) > f(x,y, \overline{\Omega}(y)) \quad \text{for } 0 < x < \infty. \]

We can construct \( \overline{\Omega}(x,y) \) to satisfy the condition (I') comparably easily. (From now on, we denote \( \Omega = \overline{\Omega} \).) Therefore it is essential to construct two functions \( \Omega(x,y), \omega(x) \) satisfying the following conditions

(E') \[ k \equiv \overline{\Omega}(x,y) + \overline{\Omega}(y,x) - f > 0 \quad \text{for } 0 < x < \infty, \quad \omega(x) \leq y < 1 \]

(I') \[ \Omega(x,\omega(x)) > \omega(x) \quad \text{for } 0 < x < \infty. \]

We put \( \overline{\Omega}(x,y) = 2xy^k(1-y). \)

In solving this problem, this function proposed by N.Kikuchi is essential.
Then we have
\[ k = 2y^{-1}(1-y)(1 + 2\lambda - x^2y^2(1-y)) \]
If we define a continuous function \( y = \omega(x) \) implicitly by
\[ y = \omega(x) \iff x^2 = y^2(1+2\lambda)/(1-y) \]
then \( k \geq 0 \) for \( 0 < x < \infty \), \( \omega(x) \leq y < 1 \). Thus the condition \( (E') \)
is satisfied (the equality in \( k \geq 0 \) is not essential).

By differentiating both sides of this relation w.r.t. \( y \), we have
\[ 2x \frac{d x}{d y} = (1/2+ \lambda)y^{1/2}(3-y)/(1-y)^2. \]

Then the condition \( (I') \) becomes
\[ 2xy^{-1}(1-y) > \frac{d x}{d y} , \]
\[ 2x \frac{d x}{d y} > y^{1/2}/(1-y) , \]
\[ (1/2+ \lambda)y^{1/2}(3-y)/(1-y)^2 > y^{1/2}/(1-y) , \]
and then
\[ \lambda > -1/2 + (1-y)/(3-y) = h(y) . \]

Since \( \sup_{0 < y < 1} h(y) = -1/6 \), for \( \lambda > -1/6 \) this inequality holds,
so the condition \( (I') \) is satisfied.

This completes the proof of Theorem 1.

2. More precise estimate for \( \lambda \)

In order to have a more precise estimate for \( \lambda \) we shall construct\( \ominus(x,y) \) by the following form.
\[ \ominus(x,y) = 2xy^{-1}(1-y)u(y) \]
And we have obtained an estimate for $\lambda$ of the following type. Theorem 2. Let $u(y)$ be a continuous function on $0 \leq y \leq 1$ such that the following conditions are satisfied

(i) of class $C^1$ and piecewise $C^2$ on $0 < y < 1$

(ii) $1 \leq u \leq 2$, $u' \leq 0$ on $0 < y < 1$

$u(1) = 1$, $\lim_{y \to 1^-} (1-y)u'(y) = 0$

(iii) $g(y) > 0$ on $0 < y < 1$.

Here $g(y)$ is defined as follows:

$v(y) = 1 + (1+y)(u-1)/(1-y) - 2yu' \quad (\geq 1 \text{ from (ii)})$

$g(y) = (3-y)/(1-y) - 2y(u'/u + v'/v)$.

Then for $\lambda > \sup_{0 < y < 1} (-u/2 + (v-yu')/g)$ there exists a continuous solution for (1) satisfying (2), (3).

In this case

$k = 2y^\frac{1}{2}(1-y)[u + 2\lambda - x^2 y^{-\frac{3}{2}} u(1-y)v]$.

As a implicit function of $k(x,y) = 0$ we take $y = \omega(x)$. That is, we define $y = \omega(x)$ implicitly by

$y = \omega(x) \iff x^2 = y^\frac{3}{2} (1+2\lambda)/u/(1-y)v$.

Differentiating this relation we have

$2x \frac{dx}{dy} = y^\frac{1}{2} \left( (u/2 + \lambda)g + p \right) / (1-y)uv$.

To satisfy the condition $(1') \cup(x,\omega(x)) > \omega(x)$

$2xy^{-\frac{1}{2}}(1-y)u > \frac{dy}{dx}$ ( $y = \omega(x)$ )

$2x \frac{dx}{dy} > y^\frac{1}{2} / (1-y)u$

$(u/2 + \lambda)g > v - yu'$.  

8
From the condition (iii) \( g > 0 \) for \( 0 < y < 1 \)
\[ \lambda > -u/2 + (v - yu')/g = h(y) \]

By the similar way to the proof of Theorem 1, we can obtain a solution

of (4) for \( \lambda > \sup_{0 < y < 1} h(y) \)

This completes the proof of Theorem 2.

Using this Theorem, we can obtain a more precise estimate for \( \lambda \). If we construct a continuous function \( u(y) \) on \( 0 \leq y \leq 1 \) satisfying (1), (ii), fortunately the condition (iii) is satisfied in most case. Then for

\[ \lambda > \sup_{0 < y < 1} h(y;u) \]

we have a solution of (1) satisfying (2), (3).

The function \( u(y) \) has characters \( u' \leq 0 \), \( u(1) = 1 \). If we take for example

\[ u = 1 + 0.18(1-y)^{\frac{1}{3}} \]

then we have \( \sup_{0 < y < 1} h = -0.1962 \ldots \)

And constructing the function \( u(y) \) to make

\[ |h(y;u) - (-0.1988)| \]

as small as possible, we can obtain the value \( \lambda > -0.1988 \ldots \)

This function \( u(y) \) was obtained almost by solving an ordinary differential equation

\[ h(y;u,u',u'') = -0.1988 \]

for an unknown function \( u(y) \).

This equation is equivalent to the original one. In fact, if \( h(y) = \lambda \), we have

\[ \Omega_x + \Omega_y \Omega(x,\omega(x)) = f(x,\omega(x),\Omega(x,\omega(x))) \]
\[ \Omega(x,\omega(x)) = \omega(x) \]
\[
\ddot{\omega} = \bigwedge_x + \bigwedge_y \omega(x) \\
= \bigwedge_x + \bigwedge_y \bigwedge \\
= f(x, \omega(x), \bigwedge(x, \omega(x))) \\
= f(x, \omega(x), \dot{\omega}(x)).
\]

This relation shows that the function \( \omega(x) \) is a solution of (4).
