

Notes on effective usage of double exponential formulas  
for numerical integration.

Hideo Toda and Harumi Ono

1. Introduction

We shall describe the results of numerical evaluation  
of an integral

$$(1-1) \quad I = \int_a^b f(x) dx$$

using the double exponential formulas (DE formulas), and  
empirical evidences derived from these results.

The DE formulas have been developed as a class of  
numerical quadrature formulas by Takahashi and Mori [1] ,  
and they offer one of the most powerful methods to evaluate  
an improper integral on  $[a, b]$  , in which the integrand is  
singular at one endpoint or both. Moreover, we shall show  
a method to evaluate difficult integrals, where the integrand  
is highly oscillating.

2. Comparison of results by some numerical integration formulas.

As a numerical comparison of formulas among DE, IMT, CADRE  
and QUAD we show in Table 2-1 the number of integrand evaluations  
and the relative error estimated from the following convergence  
criterion (2-1) by choosing 15 test cases of Patterson [3] and  
Ichida and Kiyono [4].

A convergence criterion of our program is satisfied when  
(2-1)  $|S_{i+1} - S_i| \leq \varepsilon |S_{i+1}|$

where  $S_i$  is a value of DE formula with mesh size  $h_i$  , and  $S_{i+1}$   
is a value of DE formula with mesh size  $h_{i+1} = h_i / 2$  , and  $\varepsilon$   
is some preassigned tolerance (e.g.,  $10^{-9}$  ).

## 2.1 DE formula and IMT formula

Table 2.1-1

DE	IMT
$I = \int_a^b f(x) dx$ $x = \phi(u)^*$ $I = \int_{-\infty}^{\infty} f(\phi(u)) \phi'(u) du$ $\approx I_h = h \sum_{n=-\infty}^{\infty} f(\phi(nh)) \phi'(nh)$ based on the fact that the trapezoidal rule gives the best result for $\int_{-\infty}^{\infty} g(u) du$ with mesh size $h$ .	$I = \int_0^1 f(x) dx$ $x = \psi(u) = \frac{1}{Q} \int_0^u \exp(-\frac{1}{t} - \frac{1}{1-t}) dt$ $Q = \int_0^1 \exp(-\frac{1}{t} - \frac{1}{t-1}) dt$ $I = \int_0^1 f(\psi(u)) \psi'(u) du$ $\approx S_N = \frac{1}{N} \sum_{n=1}^{N-1} f(\psi(\frac{n}{N})) \psi'(\frac{n}{N})$ based on Euler-Maclaurin summation formula.

\* where

$$(2.1-1) \quad x = \phi(u) = \tanh(\frac{\pi}{2} \sinh u) \quad \text{if} \quad I = \int_{-1}^1 f(x) dx$$

$$(2.1-2) \quad x = \phi(u) = \exp(\frac{\pi}{2} \sinh u) \quad \text{if} \quad I = \int_0^{\infty} f(x) dx$$

$$(2.1-3) \quad x = \phi(u) = \exp(u - \exp(-u)) \quad \text{if} \quad I = \int_0^{\infty} \exp(-x) f(x) dx$$

$$(2.1-4) \quad x = \phi(u) = \sinh(\frac{\pi}{2} \sinh u) \quad \text{if} \quad I = \int_{-\infty}^{\infty} f(x) dx$$

## 2.2 Choosing a quadrature formula

Table 2-1 supports the following statements:

- i) For integrals over finite intervals, if the integrand has no singularity through the interval, CADRE or QUAD gets an advantage over DE (P2, P5, P7).
- ii) For improper integrals over finite intervals with singularities at the endpoints of the interval, DE gets the best advantage and IMT gets the second best (P1, P4, P11).
- iii) For integrals over infinite and semi-infinite intervals, if the integrand is not regular at infinity, DE is better than all the other formulas (e.g.,  $\int_0^\infty \exp(-x) \cdot \log x \, dx$ ). However, if the integrand is regular at infinity, it can be reduced to the case i) by suitable change of variable (e.g.,  $\int_0^\infty \frac{1}{1+x^4} \, dx = \int_0^{\frac{\pi}{2}} \frac{\cos^2 \theta}{\cos^4 \theta + \sin^4 \theta} \, d\theta$ ). But even if DE may be used to evaluate the original integral, it will give slightly worse results than CADRE or QUAD.
- iv) For integrals with singularity close to the real axis in the interior of the interval (e.g., K1), it is hard to evaluate the integral with desired accuracy using any of all the methods presented here, and DE is the most unsuccessful among them. But by splitting the integral into two integrals at the real part of the singular point, it can be reduced to case ii).

3. Notes on usage of DE formula on digital computer.

Some notes must be necessary to effective use of DE formula.

3.1 A numerical technique by Takahashi and Mori to avoid subtractive cancellation by the factor  $(1+x)^\alpha (1-x)^\beta$ ,  $\alpha, \beta < 0$ .

In the case of integral  $\int_{-1}^1 f(x) dx$ ,  $f(x)$  having a factor  $(1+x)^\alpha (1-x)^\beta$ ,  $\alpha, \beta < 0$  (e.g.,  $f(x) = 1/\sqrt{1-x}$ ,  $1/\sqrt{\tan(\pi/2)(1+x)}$ ), the number of its significant digits decreases as  $x \rightarrow \pm 1$ . Thus the relative error in the  $f(x)$  will be greatly increased. In such a case, following Takahashi and Mori [1] p.735, we must make the change of variable to avoid the cancellation; splitting the integral into two integrals, we have

$$(3.1-1) \quad I = \int_{-1}^1 f(x) dx = \int_{-1}^0 f(x) dx + \int_0^1 f(x) dx = I_1 + I_2$$

and we make direct substitution of  $1 \pm x$  as follows:

$$(3.1-2) \quad -t = 1+x = 1 + \tanh\left(\frac{\pi}{2} \sinh u\right) = \frac{\exp\left(\frac{\pi}{2} \sinh u\right)}{\cosh\left(\frac{\pi}{2} \sinh u\right)}$$

$$t \in [-1, 0]$$

$$(3.1-3) \quad t = 1-x = 1 - \tanh\left(\frac{\pi}{2} \sinh u\right) = \frac{\exp\left(-\frac{\pi}{2} \sinh u\right)}{\cosh\left(\frac{\pi}{2} \sinh u\right)}$$

$$t \in [0, 1]$$

Then we obtain

$$(3.1-4) \quad I_1 = \int_{-1}^0 f(-1-t) dt = \int_{-\infty}^0 f(-1-t(u)) \cdot \frac{\frac{\pi}{2} \cosh u}{\cosh^2\left(\frac{\pi}{2} \sinh u\right)} du$$

$$(3.1-5) \quad I_2 = \int_0^1 f(1-t) dt = \int_0^{\infty} f(1-t(u)) \cdot \frac{\frac{\pi}{2} \cosh u}{\cosh^2\left(\frac{\pi}{2} \sinh u\right)} du$$

### 3.2 Note on mechanizing DE formula on digital computer.

The essence of the technique described above is to substitute  $\mp \exp(\pm \frac{\pi}{2} \sinh u) / \cosh(\frac{\pi}{2} \sinh u)$  directly into  $t = \mp 1-x$ . Thus, it will be of no use to avoid cancellation to make the change of variable  $x = -1-t$  for  $x \in [-1, 0]$  and  $x = 1-t$  for  $x \in [0, 1]$  in library programs and to write  $f(x)$  in its original form. Since the term  $1+x$  will be evaluated not by  $-t$  but by  $1 + (-1-t)$ , the loss of significance will be very large. Then we must transform  $f(x)$  into the expression  $g(t)$  of the independent variable  $t = -1-x$  for  $x \in [-1, 0]$ , and  $t = 1-x$  for  $x \in [0, 1]$ . For example,

$$f(x) = (1+x)^{-\frac{1}{2}}(1-x)^{-\frac{1}{3}}$$

we must make transformation as follows:

$$f(x) = g(t) = \begin{cases} (-t)^{-\frac{1}{2}}(2+t)^{-\frac{1}{3}} & t \in [-1, 0] \\ (2-t)^{-\frac{1}{2}}t^{-\frac{1}{3}} & t \in [0, 1] \end{cases}$$

The same situation holds for the integral  $\int_a^b f(x)dx$ , if  $f(x)$  has a factor  $(x-a)^\alpha(b-x)^\beta$ ,  $\alpha, \beta < 0$ . In this case we must transform  $f(x)$  into the expression of the variable  $t = -\frac{2}{b-a}(x-a)$  for  $x \in [a, \frac{a+b}{2}]$  and  $t = \frac{2}{b-a}(b-x)$  for  $x \in [\frac{a+b}{2}, b]$ .

If this transformation is very tedious, we can transform the integral into an integral over  $[0, \infty)$  by suitable change of variable (e.g.,  $x = \exp(-t)$ ), and then apply (2.1-2) or (2.1-3). For H1, by the change of variable  $x = \exp(-t)$ , we get

$$H1' \quad I = \int_0^\infty \exp(-t) \log t dt$$

In this case, there is a problem how to choose the initial step size  $h_0$  for H1. We shall consider this problem in the next section.

3.3 The initial step size  $h_0$ .

Our starting algorithm to find  $M, N$  such that

$S_0 = \sum_{n=-M}^N f(\phi(nh_0)) \cdot \phi'(nh_0)$ , where  $S_0$  is the first approximation of  $I$ , is as follows:

Input

$\varepsilon$  (some preassigned tolerance)

$h_0$  (initial step size)

Algorithm

$h \leftarrow h_0; S_0 \leftarrow f(\phi(0)) \cdot \phi'(0); N \leftarrow 0; M \leftarrow 0$

for  $n=1, 2, \dots$  do

if  $N=0$  then  $T_n \leftarrow f(\phi(nh)) \cdot \phi'(nh)$

if  $|T_n| \leq |S_0| * \max(\varepsilon * 10^{-3}, 10^{-6})$  then  $N \leftarrow n$

else  $S_0 \leftarrow S_0 + T_n$

endif

endif

if  $M=0$  then  $U_n \leftarrow f(\phi(-nh)) \cdot \phi'(-nh)$

if  $|U_n| \leq |S_0| * \max(\varepsilon * 10^{-3}, 10^{-6})$  then  $M \leftarrow n$

else  $S_0 \leftarrow S_0 + U_n$

endif

endif

endfor

next:

Thus,

$$(3.3-1) \quad |T_n| \leq |S_0| * \max(\varepsilon * 10^{-3}, 10^{-6})$$

$$|U_n| \leq |S_0| * \max(\varepsilon * 10^{-3}, 10^{-6})$$

must hold before  $nh_0, n=1, 2, \dots$ , exceeds a certain threshold value which depends on representation of number by computer.

For example, in the case of H1, we have

$$\begin{aligned} I &= \int_0^1 \log |\log x| dx = \int_{-1}^1 \frac{1}{2} \log \left| \log \frac{1+x}{2} \right| dx \\ &= \int_{-1}^0 \frac{1}{2} \log \left| \log \left( -\frac{t}{2} \right) \right| dt + \int_0^1 \frac{1}{2} \log \left| \log \frac{2-t}{2} \right| dt \end{aligned}$$

where

$$-t = \frac{\exp(\frac{\pi}{2} \sinh u)}{\cosh(\frac{\pi}{2} \sinh u)} \quad t \in [-1, 0]$$

$$t = \frac{\exp(-\frac{\pi}{2} \sinh u)}{\cosh(\frac{\pi}{2} \sinh u)} \quad t \in [0, 1]$$

Since  $2-t$  and  $2$  are considered as the same values (additive no contribution) for  $nh_o > 3.45$  with double precision arithmetic in T-56, the second integrand  $\frac{1}{2} \log \left| \log \frac{2-t}{2} \right|$  is regarded as  $\log 0$  (error message "not allowed").

In the case of P7, we have

$$\begin{aligned} I &= \int_0^1 \frac{x}{\exp x - 1} dx = \int_{-1}^1 \frac{1}{2} \cdot \frac{\frac{1+x}{2}}{\exp(\frac{1+x}{2}) - 1} dx \\ &= \int_{-1}^0 \frac{1}{2} \cdot \frac{-\frac{t}{2}}{\exp(-\frac{t}{2}) - 1} dt + \int_0^1 \frac{1}{2} \cdot \frac{\frac{2-t}{2}}{\exp(\frac{2-t}{2}) - 1} dt \end{aligned}$$

In the denominator of the first integral  $\exp(-\frac{t}{2})$  is considered to be 1 for  $nh_o \geq 3.31$ .

In both cases for large step size  $h_o$ , our starting algorithm results in failure by evaluating  $f(\phi(nh_o)) \cdot \phi'(nh_o)$  or  $f(\phi(-nh_o)) \cdot \phi'(-nh_o)$  at a point  $nh_o$  beyond the limit 3.45 or 3.31 respectively. In contrast, it can be expected that by taking  $h_o$  small enough depending on the tolerance  $\varepsilon$  (3.3-1) can hold before  $nh_o$  exceeds that threshold value. This is illustrated in Fig. 3.3-1.

## 3.4 On the criterion of convergence.

Since the error term for DE formula with mesh size  $h$  is roughly estimated (Ref. [5] p.265)

$$(3.4-1) \quad |\Delta I_h| \simeq \exp(-\frac{A}{h})$$

where  $A$  is a constant, we have

$$(3.4-2) \quad |\Delta I_{\frac{h}{2}}| \simeq |\Delta I_h|^2$$

So that if we halve the mesh size, then the number of significant digits are doubled. Thus we can usually get the desired accuracy when

$$(3.4-3) \quad |S_{i+1} - S_i| \leq \sqrt{\varepsilon} |S_{i+1}|$$

holds, except in the case where the integrand oscillates (e.g., P8 and P10).

In the above-mentioned case, however, on the safe side, we should like to test whether both

$$|S_{i+1} - S_i| \leq \varepsilon |S_{i+1}|$$

and

$$|S_{i+2} - S_{i+1}| \leq \varepsilon |S_{i+2}|$$

hold as the criteria of convergence. From Fig. 3.4-1, we see that (3.4-2) does not hold until mesh size  $h$  becomes small enough.

4. Difficult problems of integration

4.1 The restriction imposed by the number of bits for exponent.

The number of bits for exponent is usually taken to be 7 or 8. Then, for example, the integral to get the abscissas of IMT formula

$$\begin{aligned} I &= \int_0^t \exp\left(-\frac{1}{x} - \frac{1}{1-x}\right) dx \\ &= t \int_0^\infty \exp\left(-\frac{1}{t \exp(-x)}\right) \exp\left(-\frac{1}{1-t \exp(-x)}\right) \exp(-x) dx \end{aligned}$$

with  $t = 3/512, 2/512, 1/512$ , has the value far smaller than  $10^{-58}$ . Thus, if we wish to evaluate this integral using DE formula (2.1-3), our algorithm will fail, since (3.3-1) is not satisfied before  $nh=5.5$ , with this  $nh \ x = \exp(nh - \exp(-nh))$  becomes 243.7 and  $\exp(-x)$  vanishes.

Such a problem requires the use of multiple-precision arithmetic [6].

5. Conclusion

We conclude from the experiment described above that DE formulas offer a very powerful method for numerical integration, except for the special cases described in the previous section. It is recommended to use DE formulas especially for integrals over infinite or semi-infinite intervals.

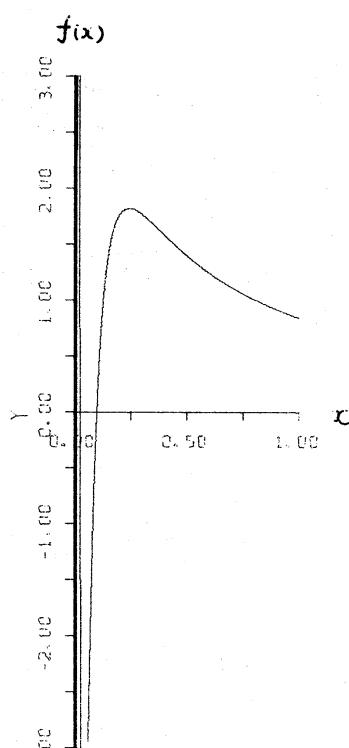

**Appendix.**

Dr. Rabinowitz presented the following problem when he visited ETL at Tsukuba on June 4, 1980.

$$I = \int_0^1 f(x) dx = \int_0^1 \frac{\sin \frac{1}{\sqrt{x}}}{\sqrt{x}} dx \approx 1.00813 41238 139$$

at  $x=0$  value=0

We will show the results obtained by DE formulas below.
