Metric positivity of direct image sheaves of differential forms

We consider a proper surjective holomorphic map \( f : X \to Y \) with connected fibers, from a complex manifold \( X \) to a normal complex space \( Y \) with \( \dim Y = m \) and \( \dim X = n + m \), and an \( f \)-ample line bundle \( E \) on \( X \). We discuss good properties of \( R^{n-p} f_{*}(\Omega_X^{m-q} \otimes E) \) or \( R^{n-p} f_{*}(\Omega_X^{m} \otimes E) \), as Kollár did for \( R^q f_{*}(K_{X/Y} \otimes E') \) with \( q \geq 0 \), where \( E' \) is a line bundle on \( X \) with weaker positivities. Our aim is to try to interpolate Kodaira-Spencer’s deformation theory and the Hodge theory by introducing a polarization and by considering adjoint-type vector bundles associated to it. The result is as follows [T].

**Theorem 1.** Let \( f : X \to Y \) and \( E \) be as above. Then

1. \( R^{n+q} f_{*}(\Omega_X^{m-q} \otimes E) = 0 \) if \( q > 0 \).
2. \( R^{n-p} f_{*}(\Omega_X^{m} \otimes E) \) is torsion free.
3. Assume \( Y \) and \( f \) are smooth. Then \( R^{n-p} f_{*}(\Omega_X^{m} \otimes E) \) is locally free.
4. Assume \( Y \) and \( f \) are smooth. Then there exists an exact sequence

\[ T_Y \otimes R^{n-p-1} f_{*}(\Omega_X^{m+1} \otimes E) \xrightarrow{\delta_{p+1}} R^{n-p} f_{*}(\Omega_X^{m} \otimes E) \xrightarrow{\tau_p} R^{n-p} f_{*}(\Omega_X^{m} \otimes E) \otimes K_Y^{-1} \to 0, \]

which is induced by a natural inclusion \( \Omega_Y^{p} \otimes f^* K_Y \subset \Omega_X^{p+m} \), i.e., \( \Omega_Y^{p} \subset \Omega_X^{p+m} \otimes f^* K_Y^{-1} \).

Moreover the surjection \( \tau_p \) splits.

**Theorem 2.** In Theorem 1, assume \( Y \) and \( f \) are smooth, and assume \( E \) admits a Hermitian metric \( h \) whose curvature is semi-positive \( \sqrt{-1} \Theta_h \geq 0 \) on \( X \) and positive \( \sqrt{-1} \Theta_h |_{X_y} > 0 \) on every fiber \( X_y \). Then for every \( 0 \leq p \leq n \), the vector bundle \( R^{n-p} f_{*}(\Omega_X^{m} \otimes E) \otimes K_Y^{-1} \) is Griffiths semi-positive. Moreover if \( E \) is positive on \( X \), then \( R^{n-p} f_{*}(\Omega_X^{m} \otimes E) \otimes K_Y^{-1} \) is Griffiths positive, if it is non-zero.

In case when \( f : X \to Y \) with \( Y \) smooth, parametrizes canonically polarized manifolds i.e., every \( K_X \) is ample, we can take \( E = K_{X/Y} \) in Theorem 1, and then \( (R^{n-p} f_{*}(\Omega_X^{m} \otimes E))^* = R^{1-p} f^{*} T_{X/Y}^{n+1} \) by the relative duality. When \( p = 1 \), \( R^1 f_{*} T_{X/Y}^{n+1} \) is the sheaf where the Kodaira-Spencer class lives. By a recent remarkable result of Schumacher, \( K_{X/Y} \) is semi-positive on \( X \) with respect to the fiberwise Kähler-Einstein metrics \( \omega_{y} \); the Hermitian metric \( h \) on \( K_{X/Y} \) so that \( h|_{X_y} = (\det \omega_y)^{-1} \) on every fiber \( X_y \). Moreover if the parametrization is effective, \( K_{X/Y} \) is positive. Thus we can apply Theorem 2 for such kind of \( (E,h) = (K_{X/Y},h) \). Earlier works of Siu and Schumacher tried to determine the sign of the curvature of the Weil-Petersson metric on \( T_Y \). More recently, Schumacher also gives a curvature formula for \( R^{n-p} f_{*}(\Omega_X^{m} \otimes K_{X/Y}^{m}) \) on some open subset of \( Y \).

Regarding the method of proof, our argument is basically analytic. We put an appropriate Hermitian metric \( h \) on \( E \) with positive curvature, and we develop a theory of harmonic integrals for the cohomology groups \( H^q(X, \Omega_X^{m} \otimes E) \) with \( p + q = \dim X \) with respect to \( h \) and a Kähler form \( \omega_X = \sqrt{-1} \Theta_h \) on \( X \). Positive line bundle valued middle degree harmonic forms are special by the following reason. With respect to a Kähler form \( \omega_X = \sqrt{-1} \Theta_h \) and \( h \), Akizuki-Nakano’s formula on bidegree \( (p,q) \) with \( p + q = \dim X \) is \( \Delta \beta = \Delta \beta_h \), i.e., there is no curvature term \( [\sqrt{-1}e(\Theta_h), \Lambda_{\omega_X}] \). Thus, at least in case \( X \) is

compact, if $u \in C^{p,q}(X, E)$ is $\Delta_{\overline{\partial}}$-harmonic, it is $\Delta_{\partial_{h}}$-harmonic too, and hence $u$ is not only $\overline{\partial}$-closed, but also $D_{h} = \partial_{h} + \overline{\partial}$ closed. We will have several vanishing like this, and have a theory of harmonic integrals when $Y$ is localized as follows. Letting $Y$ to be Stein, $H^{q}(X, \Omega_{X}^{p} \otimes E)$ with $p + q = \dim X$ is represented by

$$H^{p,q}(X, \omega_{X}, E, h) = \{ u \in C^{p,q}(X, E); \overline{\partial}u = \partial_{h}u = 0, u \text{ is } \omega_{X}\text{-primitive},$$

$$u \wedge ds = 0 \text{ for any } s \in H^{0}(X, \mathcal{O}_{X}) \},$$

where $\partial_{h}$ is the formal adjoint of $\overline{\partial}$ with respect to $\omega_{X}$ and $h$. Since $X$ is non-compact, we need practically a boundary condition to obtain a reasonable harmonic representation. The final condition $u \wedge ds = 0$ plays a role of the so-called $\overline{\partial}$-Neumann condition. We can moreover show that $H^{p,q}(X, \omega_{X}, E, h)$ becomes an $H^{0}(X, \mathcal{O}_{X})$-module in a natural way, which will lead the torsion freeness of $R^{q}f_{*}(\Omega_{X}^{p} \otimes E)$ via the above harmonic representation.

A Hermitian metric $g = g_{Y}$ on $R^{n-p}f_{*}(\Omega_{X/Y}^{p+m} \otimes E) \otimes K_{Y}^{-1}$ in Theorem 2 can be described as follows. The curvature of $h$ on $E$ gives a Kähler form $\omega_{g} = \sqrt{-1}\Theta_{h}|_{X_{y}}$ on every fiber $X_{y}$. We then consider a Hermitian inner product on $C^{p,n-p}(X, E_{y})$ with respect to $\omega_{g}$ and $h_{y} = h|_{X_{y}}$, and put a “Hermitian metric” $g$ on $R^{n-p}f_{*}(\Omega_{X/Y}^{p} \otimes E)$, via the fiberwise harmonic representation with respect to $\omega_{g}$ and $h_{y}$. Regarding $R^{n-p}f_{*}(\Omega_{X/Y}^{p} \otimes E) \otimes K_{Y}^{-1}$ as a locally free subsheaf of $R^{n-p}f_{*}(\Omega_{X/Y}^{p} \otimes E)$ by the splitting in Theorem 1 (4), we put a “Hermitian metric” on $R^{n-p}f_{*}(\Omega_{X/Y}^{p} \otimes E) \otimes K_{Y}^{-1}$. Then we can show that this defines a Hermitian metric on $R^{n-p}f_{*}(\Omega_{X/Y}^{p} \otimes E) \otimes K_{Y}^{-1}$ in the usual sense.

The computation of the curvature of the metric $g$ on $R^{n-p}f_{*}(\Omega_{X/Y}^{p+m} \otimes E) \otimes K_{Y}^{-1}$ will be done by trying to generalize that in Berndtsson [B] i.e. in case $p = n$. For simplicity, we let $Y$ be a unit disc in $\mathbb{C}$ with coordinate $t$, and $\omega_{X} = \sqrt{-1}\Theta_{h}|_{X_{y}} > 0$. Let $u \in C^{p,n-p}(X, E)$ and suppose that $u|_{X_{y}}$ is primitive on every fiber and $\partial_{h}u = \xi \wedge dt$, $\overline{\partial}u = \eta \wedge dt$ with $\xi \in C^{p,n-p}(X, E), \eta \in C^{p-1,n-p+1}(X, E)$. (This is not really correct as it stands.) We put $\|f_{*}u\|^{2} \in C^{\infty}(Y, \mathbb{R})$ by $\|f_{*}u\|(t) = \|u|_{X_{t}}\|$: the $L^{2}$-norm of $u|_{X_{t}}$ with respect to the metrics $\omega_{g}$ and $h_{y}$. Then the curvature of $g$ on $R^{n-p}f_{*}(\Omega_{X/Y}^{p} \otimes E) \otimes K_{Y}^{-1}$ is like $-\sqrt{-1}\partial\overline{\partial}\|f_{*}u\|^{2}$, and

$$-\sqrt{-1}\frac{\partial^{2}\|f_{*}u\|^{2}}{\partial t \partial \overline{t}}|_{t=0} = f_{*}(ch\sqrt{-1}\Theta_{h} \wedge u \wedge \overline{u})|_{t=0} - \|\xi|_{X_{t}}\|^{2} + \|\eta|_{X_{t}}\|^{2},$$

where $c$ is a constant so that the pointwise pairing $c\sqrt{-1}\Theta_{h} \wedge u \wedge \overline{u}$ is positive definite if $u$ is primitive with respect to $\omega_{X}$, and where $f_{*}(ch\sqrt{-1}\Theta_{h} \wedge u \wedge \overline{u})|_{t=0} = \varphi(0)$ when we write the push-forward $(1, 1)$-current $f_{*}(ch\sqrt{-1}\Theta_{h} \wedge u \wedge \overline{u}) = \varphi(t)^{2}\sqrt{-1}dtd \wedge \overline{d}t$. We would like to show that the right hand side is positive. In case $p = n$ ([B]), the first term is positive since $u$ is primitive simply by a bidegree reason, and one can manage to delete $\xi|_{X_{t}} = 0$. Thus $-\sqrt{-1}\partial\overline{\partial}\|f_{*}u\|^{2} > 0$. One might think for general $p$ that the first term is positive as well, since $\sqrt{-1}\Theta_{h} > 0$. However in general, it is not automatic, since $u$ is not primitive at all. Thanks to detailed analysis of harmonic representatives, we can reduce it to primitive forms for some parts, but (it seems) we can do it completely. We have a difficulty to show the Nakano positivity of $R^{n-p}f_{*}(\Omega_{X/Y}^{p} \otimes E) \otimes K_{Y}^{-1}$, caused by this “non-primitive issue”. But finally we can manage to show that $f_{*}(ch\sqrt{-1}\Theta_{h} \wedge u \wedge \overline{u})|_{t=0} > 0$ and $\|\xi|_{X_{t}}\| \leq \|\eta|_{X_{t}}\|$, and then the Griffiths positivity.
