EVERY POSET APPEARS AS THE ATOM SPECTRUM OF SOME
GROTHENDIECK CATEGORY

RYO KANDA

ABSTRACT. This report is a survey of our result in [Kan15b]. We introduce systematic methods

to construct Grothendieck categories from colored quivers and develop a theory of the special-

isation orders on the atom spectra of Grothendieck categories. We showed that every partially

ordered set is realized as the atom spectrum of some Grothendieck category, which is an analog

of Hochster's result in commutative ring theory. In this report, we explain techniques in the

proof by using examples.

1. INTRODUCTION

This report is a survey of our result in [Kan15b].

There are important Grothendieck categories appearing in representation theory of rings and
algebraic geometry: the category Mod $A$ of (right) modules over a ring $A$, the category $\text{QCoh } X$
of quasi-coherent sheaves on a scheme $X$ ([Con00, Lem 2.1.7]), and the category of quasi-coherent
sheaves on a noncommutative projective space introduced by Verevkin [Ver92] and Artin and
Zhang [AZ94]. Furthermore, by using the Gabriel–Popescu embedding ([PG64, Proposition]), it is
shown that every Grothendieck category can be obtained as the quotient category of the category
of modules over some ring by some localizing subcategory.

In commutative ring theory, Hochster characterized the topological spaces appearing as the
prime spectra of commutative rings with Zariski topologies ([Hoc69, Theorem 6 and Proposition
10]). Speed [Spe72] pointed out that Hochster's result gives the following characterization of the
partially ordered sets appearing as the prime spectra of commutative rings.

Theorem 1.1 (Hochster [Hoc69, Proposition 10] and Speed [Spe72, Corollary 1]). Let $P$ be a
partially ordered set. Then $P$ is isomorphic to the prime spectrum of some commutative ring with
the inclusion relation if and only if $P$ is an inverse limit of finite partially ordered sets in the
category of partially ordered sets.

We showed a theorem of the same type for Grothendieck categories. In [Kan12] and [Kan15a],
we investigated Grothendieck categories by using the atom spectrum $\text{ASpec } A$ of a Grothendieck
category $A$. It is the set of equivalence classes of monoform objects, which generalizes the prime
spectrum of a commutative ring.

In fact, our main result claims that every partially ordered set is realized as the atom spectrum
of some Grothendieck categories.

Theorem 1.2. Every partially ordered set is isomorphic to the atom spectrum of some Grothendieck

category.

In this report, we explain key ideas to show this theorem by using examples. For more details,
we refer the reader to [Kan15b].
2. Atom Spectrum

In this section, we recall the definition of atom spectrum and fundamental properties. Throughout this report, let \( \mathcal{A} \) be a Grothendieck category. It is defined as follows.

**Definition 2.1.** An abelian category \( \mathcal{A} \) is called a *Grothendieck category* if it satisfies the following conditions.

1. \( \mathcal{A} \) admits arbitrary direct sums (and hence arbitrary direct limits), and for every direct system of short exact sequences in \( \mathcal{A} \), its direct limit is also a short exact sequence.
2. \( \mathcal{A} \) has a generator \( G \), that is, every object in \( \mathcal{A} \) is isomorphic to a quotient object of the direct sum of some (possibly infinite) copies of \( G \).

**Definition 2.2.** A nonzero object \( H \) in \( \mathcal{A} \) is called *monoform* if for every nonzero subobject \( L \) of \( H \), there does not exist a nonzero subobject of \( H \) which is isomorphic to a subobject of \( H/L \).

Monoform objects have the following properties.

**Proposition 2.3.** Let \( H \) be a monoform object in \( \mathcal{A} \). Then the following assertions hold.

1. Every nonzero subobject of \( H \) is also monoform.
2. \( H \) is uniform, that is, for every nonzero subobjects \( L_1 \) and \( L_2 \) of \( H \), we have \( L_1 \cap L_2 \neq 0 \).

**Definition 2.4.** For monoform objects \( H \) and \( H' \) in \( \mathcal{A} \), we say that \( H \) is *atom-equivalent* to \( H' \) if there exists a nonzero subobject of \( H \) which is isomorphic to a subobject of \( H' \).

**Remark 2.5.** The atom equivalence is an equivalence relation between monoform objects in \( \mathcal{A} \) since every monoform object is uniform.

Now we define the notion of atoms, which was originally introduced by Storrer [Sto72] in the case of module categories.

**Definition 2.6.** Denote by \( \text{ASpec} \mathcal{A} \) the quotient set of the set of monoform objects in \( \mathcal{A} \) by the atom equivalence. We call it the *atom spectrum* of \( \mathcal{A} \). Elements of \( \text{ASpec} \mathcal{A} \) are called *atoms* in \( \mathcal{A} \). The equivalence class of a monoform object \( H \) in \( \mathcal{A} \) is denoted by \( \overline{H} \).

**Remark 2.7.** Every simple object is monoform. Two simple objects are atom-equivalent to each other if and only if they are isomorphic. Therefore we have an embedding

\[
\frac{\text{simple objects in } \mathcal{A}}{\cong} \hookrightarrow \text{ASpec} \mathcal{A}.
\]

If \( \mathcal{A} = \text{Mod} A \) for a right artinian ring \( A \), then these two things are the same.

The following proposition shows that the atom spectrum of a Grothendieck category is a generalization of the prime spectrum of a commutative ring.

**Proposition 2.8** ([Sto72, p. 631]). Let \( R \) be a commutative ring. Then the map \( \text{Spec} R \to \text{ASpec}(\text{Mod} R) \) given by \( p \mapsto (R/p) \) is a bijection.

The notions of support is also generalized as follows.

**Definition 2.9.** Let \( M \) be an object in \( \mathcal{A} \). Define the *atom support* of \( M \) by

\[
\text{ASupp} M = \{ \overline{H} \in \text{ASpec} \mathcal{A} \mid H \text{ is a subquotient of } M \}.
\]

The following proposition is a generalization of well known results in commutative ring theory.

**Proposition 2.10.**

1. Let \( 0 \to L \to M \to N \to 0 \) be an exact sequence in \( \mathcal{A} \). Then

\[
\text{ASupp} M = \text{ASupp} L \cup \text{ASupp} N.
\]

2. Let \( \{M_{\lambda}\}_{\lambda \in \Lambda} \) be a family of objects in \( \mathcal{A} \). Then

\[
\text{ASupp} \bigoplus_{\lambda \in \Lambda} M_{\lambda} = \bigcup_{\lambda \in \Lambda} \text{ASupp} M_{\lambda}.
\]
A partial order on the atom spectrum is defined by using atom support.

**Definition 2.11.** Let $\alpha$ and $\beta$ be atoms in $A$. We write $\alpha \leq \beta$ if every object $M$ in $A$ satisfying $\alpha \in \text{ASupp } M$ also satisfies $\beta \in \text{ASupp } M$.

**Proposition 2.12.** The relation $\leq$ on $\text{ASpec } A$ is a partial order.

In the case where $A$ is the category of modules over a commutative ring $R$, the notion of atom support and the partial order on the atom spectrum coincide with support and the inclusion relation between prime ideals, respectively, through the bijection in Proposition 2.8.

3. **CONSTRUCTION OF GROTHENDIECK CATEGORIES**

In order to construct Grothendieck categories, we use colored quivers.

**Definition 3.1.** A colored quiver is a sextuple $\Gamma = (Q_0, Q_1, C, s, t, u)$ satisfying the following conditions.

1. $Q_0, Q_1,$ and $C$ are sets, and $s: Q_1 \to Q_0$, $t: Q_1 \to Q_0$, and $u: Q_1 \to C$ are maps.
2. For each $v \in Q_0$ and $c \in C$, the number of arrows $r$ satisfying $s(r) = v$ and $u(r) = c$ is finite.

We regard the colored quiver $\Gamma$ as the quiver $(Q_0, Q_1, s, t)$ with the color $u(r)$ on each arrow $r \in Q_1$.

From now on, we fix a field $K$. From a colored quiver, we construct a Grothendieck category as follows.

**Definition 3.2.** Let $\Gamma = (Q_0, Q_1, C, s, t, u)$ be a colored quiver. Denote a free $K$-algebra on $C$ by $F_C = K\langle f_c | c \in C \rangle$. Define a $K$-vector space $M_{\Gamma}$ by $M_{\Gamma} = \bigoplus_{v \in Q_0} x_vK$, where $x_vK$ is a one-dimensional $K$-vector space generated by an element $x_v$. Regard $M_{\Gamma}$ as a right $F_C$-module by defining the action of $f_c \in F_C$ as follows: for each vertex $v$ in $Q_0$,

$$x_v \cdot f_c = \sum_r x_{t(r)},$$

where $r$ runs over all the arrows $r \in Q_1$ with $s(r) = v$ and $u(r) = c$. Denote by $A_{\Gamma}$ the smallest full subcategory of $\text{Mod } F_C$ which contains $M_{\Gamma}$ and is closed under submodules, quotient modules, and direct sums.

The category $A_{\Gamma}$ defined above is a Grothendieck category. The following proposition is useful to describe the atom spectrum of $A_{\Gamma}$.

**Proposition 3.3.** Let $\Gamma = (Q_0, Q_1, C, s, t, u)$ be a colored quiver. Then $\text{ASpec } A_{\Gamma}$ is isomorphic to the subset $\text{ASupp } M_{\Gamma}$ of $\text{ASpec } (\text{Mod } F_C)$ as a partially ordered set.

**Example 3.4.** Define a colored quiver $\Gamma = (Q_0, Q_1, C, s, t, u)$ by $Q_0 = \{v, w\}$, $Q_1 = \{r\}$, $C = \{c\}$, $s(r) = v$, $t(r) = w$, and $u(r) = c$. This is illustrated as

```
v  c  w
```

Then we have $F_C = K\langle f_c \rangle = K[f_c]$, $M_{\Gamma} = x_vK \oplus x_wK$ as a $K$-vector space, and $x_vf_c = x_w$, $x_wf_c = 0$. The subspace $L = x_wK$ of $M_{\Gamma}$ is a simple $F_C$-submodule, and $L$ is isomorphic to $M_{\Gamma}/L$ as an $F_C$-module. Hence we have

$$\text{ASpec } A_{\Gamma} = \text{ASupp } M_{\Gamma} = \text{ASupp } L \cup \text{ASupp } \frac{M_{\Gamma}}{L} = \{L\}.$$
Example 3.5. Let $\Gamma = (Q_0, Q_1, C, s, t, u)$ be the colored quiver
\[ \xymatrix{ v & c \ar@{->}[d] & w \ar@{->}[d] \cr & c & } \]
and let $N = x_v K$ and $L = x_w K$. Then we have an exact sequence
\[ 0 \to L \to M_{\Gamma} \to N \to 0 \]
of $K$-vector spaces and this can be regarded as an exact sequence in $\text{Mod} F_C$. Hence we have
\[ \text{ASpec } A_{\Gamma} = \text{ASupp } M_{\Gamma} = \text{ASupp } L \cup \text{ASupp } N = \{ L, N \}, \]
where $L \neq N$.

In order to realize a partially ordered set with nontrivial partial order, we use an infinite colored quiver.

Example 3.6. Let $\Gamma = (Q_0, Q_1, C, s, t, u)$ be the colored quiver
\[ v_0 \xrightarrow{c_0} v_1 \xrightarrow{c_1} \cdots \]
Let $L$ be the simple $F_{C^\sim}$-module defined by $L = K$ as a $K$-vector space and $L f_{c_0} = 0$ for each $i \in \mathbb{Z}_{\geq 0}$. Then we have $\text{ASpec } A_{\Gamma} = \{ M_{\Gamma}, \overline{L} \}$, where $M_{\Gamma} < L$.

Definition 3.7. For a colored quiver $\Gamma = (Q_0, Q_1, C, s, t, u)$, define the colored quiver $\tilde{\Gamma} = (\tilde{Q}_0, \tilde{Q}_1, \tilde{C}, \tilde{s}, \tilde{t}, \tilde{u})$ as follows.

1. $\tilde{Q}_0 = \mathbb{Z}_{\geq 0} \times Q_0$.
2. $\tilde{Q}_1 = (\mathbb{Z}_{\geq 0} \times Q_1) \sqcup \{ r_{v, v}^i \mid i \in \mathbb{Z}_{\geq 0}, v, v' \in Q_0 \}$.
3. $\tilde{C} = C \sqcup \{ c_{v, v}^i \mid i \in \mathbb{Z}_{\geq 0}, v, v' \in Q_0 \}$.
4. (a) For each $\tilde{r} = (i, r) \in \mathbb{Z}_{\geq 0} \times Q_1 \subseteq \tilde{Q}_1$, let $\tilde{s}(\tilde{r}) = (i, s(r)), \tilde{t}(\tilde{r}) = (i, t(r))$, and $\tilde{u}(\tilde{r}) = u(r)$.
   (b) For each $\tilde{r} = r_{v, v}^i \in \tilde{Q}_1$, let $\tilde{s}(\tilde{r}) = (i, v), \tilde{t}(\tilde{r}) = (i + 1, v')$, and $\tilde{u}(\tilde{r}) = c_{v, v}^i$.

The colored quiver $\tilde{\Gamma}$ is represented by the diagram
\[ \Gamma \implies \tilde{\Gamma} \implies \cdots \]

Lemma 3.8. Let $\Gamma$ be a colored quiver. Let $\tilde{\Gamma} = (\tilde{Q}_0, \tilde{Q}_1, \tilde{C}, \tilde{s}, \tilde{t}, \tilde{u})$ be the colored quiver
\[ \Gamma \implies \tilde{\Gamma} \implies \cdots \]
Then we have
\[ \text{ASpec } A_{\tilde{\Gamma}} = (M_{\tilde{\Gamma}}) \sqcup \text{ASpec } A_{\Gamma} \]
as a subset of $\text{ASpec } (\text{Mod } F_{\tilde{C}})$, where $M_{\tilde{\Gamma}}$ is the smallest element of $\text{ASpec } A_{\tilde{\Gamma}}$.

Example 3.9. Define a sequence $\{ \Gamma_i \}_{i=0}^{\infty}$ of colored quivers as follows.

1. $\Gamma_0$ is the colored quiver
\[ v \xrightarrow{c} \]
2. For each $i \in \mathbb{Z}_{\geq 0}$, let $\Gamma_{i+1}$ be the colored quiver
\[ \Gamma_i \implies \Gamma_{i+1} \implies \cdots \]
Let $\Gamma$ be the disjoint union of $\{ \Gamma_i \}_{i=0}^{\infty}$, that is, $\Gamma$ is the colored quiver defined by the diagram
\[ \Gamma_0 \Gamma_1 \cdots \]
Then we have
\[ \text{ASpec } A_{\Gamma} = \{ M_{\Gamma_0} > M_{\Gamma_1} > \cdots \}. \]
Since the partially ordered set $\text{ASpec } A_{\Gamma}$ has no minimal element, it does not appear as the prime spectrum of a commutative ring.
We refer the reader to [Kan15b] for more constructions of Grothendieck categories to show Theorem 1.2.

4. CONSEQUENCES

It is known that every Grothendieck category $\mathcal{A}$ can be obtained as the quotient category of the category of modules over some ring $A$ by some localizing subcategory. Since we have a fully faithful functor $A \to \text{Mod } A$, this result is called the Gabriel–Popescu embedding.

**Theorem 4.1** (Gabriel and Popescu [PG64, Proposition]). Let $A$ be a Grothendieck category, $G$ a generator of $\mathcal{A}$, and $A_0 = \text{End}_A(G)$. Then there exists a localizing subcategory $\mathcal{X}$ of $\text{Mod } A$ such that $\mathcal{A}$ is equivalent to $(\text{Mod } A)/\mathcal{X}$.

We can deduce the following result on the atom spectra of module categories.

**Corollary 4.2.** For every Grothendieck category $\mathcal{A}$, there exists a ring $\Lambda$ such that $\text{ASpec } \mathcal{A}$ is isomorphic to some downward-closed subset of $\text{ASpec}(\text{Mod } A)$.

In particular, the open interval $(0, 1)$ in $\mathbb{R}$ can be embedded as a downward-closed subset into the atom spectrum of some module category of a ring. This does not happen if we restrict rings to be commutative.

5. ACKNOWLEDGMENTS

The author would like to express his deep gratitude to his supervisor Osamu Iyama for his elaborated guidance. The author thanks Shiro Goto for his valuable comments.
