# Presentations of (immersed) surface-knots by marked graph diagrams

Jieon Kim Osaka city University/JSPS

## 1 Introduction

An immersed surface-link is a generically immersed closed oriented surface in the 4-space  $\mathbb{R}^4$ . When the surface has only one component, it is also called an immersed surface-knot. When the surface consists of 2-spheres, it is also called an immersed sphere-link or simply an immersed 2-link. When the immersion is an embedding, it is also called a surface-link. Two (immersed) surface-links  $\mathcal{L}$  and  $\mathcal{L}'$  are equivalent if there is an orientation-preserving auto-homeomorphism h of  $\mathbb{R}^4$  sending  $\mathcal{L}$  to  $\mathcal{L}'$  orientation-preservingly. A normal form of an immersed surface-link introduced by S. Kamada and K. Kawamura in [5] is used to define a marked graph diagram of an immersed surface-link. In [6], we extend the method of presenting surface-links by marked graph diagrams to presenting immersed surface-links. We also give some local moves on marked graph diagrams that preserve the ambient isotopy classes of their presenting immersed surface-links, which are extension of moves given by Yoshikawa [19] for presentation of embedded surface-links.

## 2 Marked graph representation of immersed surface-links

In this section, we review (oriented) marked graph diagrams representing immersed surfacelinks described in [6]. A marked graph is a 4-valent graph in  $\mathbb{R}^3$  each of whose vertices is a vertex with a marker looks like  $\checkmark$ . Two marked graphs are said to be *equivalent* if

they are ambient isotopic in  $\mathbb{R}^3$  with keeping the rectangular neighborhoods of markers. As usual, a marked graph in  $\mathbb{R}^3$  can be described by a link diagram on  $\mathbb{R}^2$  with some 4-valent vertices equipped with markers, called a *marked graph diagram*. An *orientation* of a marked graph G in  $\mathbb{R}^3$  is a choice of an orientation for each edge of G. An orientation of a marked graph G is said to be *consistent* if every vertex in G looks like f. A marked

graph G in  $\mathbb{R}^3$  is said to be *orientable* if G admits a consistent orientation. Otherwise, it is said to be *non-orientable*. By an *oriented marked graph* we mean an orientable marked graph in  $\mathbb{R}^3$  with a fixed consistent orientation. Two oriented marked graphs are said to be *equivalent* if they are ambient isotopic in  $\mathbb{R}^3$  with keeping the rectangular neighborhood, marker and consistent orientation. For  $t \in \mathbb{R}$ , we denote by  $\mathbb{R}^3_t$  the hyperplane of  $\mathbb{R}^4$  whose fourth coordinate is equal to  $t \in \mathbb{R}$ , i.e.,  $\mathbb{R}^3_t = \{(x_1, x_2, x_3, x_4) \in \mathbb{R}^4 \mid x_4 = t\}$ . An immersed surface-link  $\mathcal{L} \subset \mathbb{R}^4 = \mathbb{R}^3 \times \mathbb{R}$  can be described in terms of its *cross-sections*  $\mathcal{L}_t = \mathcal{L} \cap \mathbb{R}^3_t$ ,  $t \in \mathbb{R}$  (cf. [3]). It is shown [5] that any immersed surface-link  $\mathcal{L}$ , there is an immersed surface-link  $\mathcal{L}' \subset \mathbb{R}^3[-2, 2]$  satisfying the following conditions:

- (1) The intersections  $\mathcal{L}'_1$  and  $\mathcal{L}'_{-1}$  are H-trivial links;
- (2) All saddle points of  $\mathcal{L}'$  are in  $\mathbb{R}^3[0]$ ;
- (3) All maximal points of  $\mathcal{L}'$  are in  $\mathbb{R}^3[2]$ ;
- (4) All minimal points of  $\mathcal{L}'$  are in  $\mathbb{R}^3[-2]$ ;
- (5) The intersections  $\mathcal{L}' \cap (\mathbb{R}^3[1,2])$  and  $\mathcal{L}' \cap (\mathbb{R}^3[-2,-1])$  are disjoint unions of a disjoint system of trivial knot cones and a disjoint system of Hopf link cones.

We call  $\mathcal{L}'$  a normal form of  $\mathcal{L}$ . Let  $\mathcal{L}$  be an immersed surface-link in  $\mathbb{R}^4$ , and  $\mathcal{L}'$  a normal form of  $\mathcal{L}$ . Then  $\mathcal{L}'_0$  is a spatial 4-valent regular graph in  $\mathbb{R}^3_0$ . We give a marker at each 4-valent vertex (saddle point) that indicates how the saddle point opens up above as illustrated in Fig. 1. We choose an orientation for each edge of  $\mathcal{L}'_0$  that coincides with the induced orientation on the boundary of  $\mathcal{L}' \cap \mathbb{R}^3 \times (-\infty, 0]$  from the orientation of  $\mathcal{L}'$ . The resulting oriented marked graph G is called an oriented marked graph of  $\mathcal{L}$ . As usual, G is described by a link diagram D with rigid marked vertices. Such a diagram D is called an oriented marked graph diagram or an oriented ch-diagram (cf. [17]) of  $\mathcal{L}$ .

Figure 1: Marking of a vertex

Let D be an oriented marked graph diagram. We obtain two links  $L_{-}(D)$  and  $L_{+}(D)$ from D by replacing each marked vertex in D as shown in Fig. 2. Links  $L_{-}(D)$  and  $L_{+}(D)$ are also called the *negative resolution* and the *positive resolution* of D, respectively. By replacing a neighborhood of each marked vertex  $v_i$   $(1 \le i \le n)$  with an oriented band  $B_i$  as illustrated in Fig. 2. Denote the disjoint union  $B_1 \sqcup \cdots \sqcup B_n$  of bands by  $\mathcal{B}(D)$ . A link L is H-trivial if L is a split union of trivial knots and Hopf links. A marked graph diagram D is said to be H-admissible if both resolutions  $L_{-}(D)$  and  $L_{+}(D)$  are H-trivial classical link diagrams as shown in Fig. 3.

From now on, we recall how to construct an immersed surface-link  $\mathcal{L}$  in  $\mathbb{R}^4$  from a given H-admissible oriented marked graph diagram (cf. [5, 6]). Let D be an H-admissible oriented marked graph diagram. We define a surface-link  $\mathcal{F}(D) \subset \mathbb{R}^3 \times [-1, 1]$ , called the proper surface associated with D, by

Figure 2: Marked vertex resolutions

Figure 3: An H-admissible marked graph diagram

$$(\mathbb{R}^{3}_{t}, \mathcal{F}(D) \cap \mathbb{R}^{3}_{t}) = \begin{cases} (\mathbb{R}^{3}, L_{+}(D)) & \text{for } 0 < t \leq 1, \\ (\mathbb{R}^{3}, L_{-}(D) \cup \mathcal{B}(D)) & \text{for } t = 0, \\ (\mathbb{R}^{3}, L_{-}(D)) & \text{for } -1 \leq t < 0. \end{cases}$$

It is known that a marked graph diagram D is orientable if and only if the proper surface  $\mathcal{F}(D)$  associated with D is an orientable surface. Since D has a consistent orientation, the resolutions  $L_+(D)$  and  $L_-(D)$  have the orientations induced from the orientation of D. We choose an orientation for the proper surface  $\mathcal{F}(D)$  so that the induced orientation of the cross-section  $L_+(D) = \mathcal{F}(D)_1 = \mathcal{F}(D) \cap \mathbb{R}^3_1$  at t = 1 matches the orientation of  $L_+(D)$ . Let [a, b] be a closed interval with a < b. For a link L, let  $\hat{L} * [a, b]$  (or  $\check{L} * [a, b]$ ) be a cone with L[a] (or L[b]) as the base and a point in  $\mathbb{R}^3[b]$  (or  $\mathbb{R}^3[a]$ ), respectively. Let  $H = (O_1 \cup \cdots \cup O_m) \cup (P_1 \cup \cdots \cup P_n)$  be an H-trivial link in  $\mathbb{R}^3$ , where  $O_i$  is a trivial knot and  $P_j$  is a Hopf link for  $i = 1, \ldots, m, j = 1, \ldots, n$ .

- Let  $H_{\wedge}[a, b]$  be a disjoint union of a disjoint system of trivial knot comes  $\hat{O}_i * [a, b](i = 1, ..., m)$  and a disjoint system of Hopf link comes  $\hat{P}_j * [a, b](j = 1, ..., n)$  in  $\mathbb{R}^3[a, b]$ .
- Let  $H_{\vee}[a, b]$  be a disjoint union of a disjoint system of trivial knot comes  $\check{O}_i * [a, b](i = 1, \ldots, m)$  and a disjoint system of Hopf link comes  $\check{P}_j * [a, b](j = 1, \ldots, n)$  in  $\mathbb{R}^3[a, b]$ .

By capping off  $\mathcal{F}(D)$  with  $L_+(D)_{\wedge}[1,2]$  and  $L_-(D)_{\vee}[-2,-1]$ , we obtain an oriented immersed surface-link  $\mathcal{S}(D)$  in  $\mathbb{R}^4$ . We call the oriented immersed surface-link  $\mathcal{S}(D)$  the oriented immersed surface-link associated with D. It is straightforward from the construction of  $\mathcal{S}(D)$  that D is an oriented marked graph diagram of the oriented immersed surface-link  $\mathcal{S}(D)$ .

**Definition 2.1.** An immersed surface-link  $\mathcal{L}$  is *presented* by an H-admissible marked graph diagram D if  $\mathcal{L}$  is ambient isotopic to  $\mathcal{S}(D)$  constructed from D.

**Theorem 2.2.** Let  $\mathcal{L}$  be an immersed surface-link. Then there is an H-admissible marked graph diagram D such that  $\mathcal{L}$  is presented by D.

We discuss moves on marked graph diagrams which preserve the ambient isotopy classes of the immersed surface-links presented by the diagrams.

Figure 4: Moves of Type I

The moves depicted in Fig. 4 on marked graph diagrams are called moves of type I, which do not change the equivalence classes of marked graphs in  $\mathbb{R}^3$ .

The moves depicted in Fig. 5 on marked graph diagrams are called moves of type II, which change the equivalence classes of marked graphs in  $\mathbb{R}^3$ . When a marked graph diagram D is H-admissible (or admissible) then the result obtained from D by any move of type II is also H-admissible (or admissible) and the immersed surface-link (or surface-link) presented by the diagrams are ambient isotopic, respectively.

It is known that two admissible marked graph diagrams present ambinet isitopic surface-links if and only if they are related by the moves of type I and II (cf. [14, 18, 19]). These moves are called *Yoshikawa moves*.

Figure 5: Moves of Type II

Let D be a link diagram of an H-trivial link L. A crossing point p of D is an *unlinking* crossing point if it is a crossing between two components of the same Hopf link of L and if the crossing change at p makes the Hopf link into a trivial link.

**Definition 2.3.** Let D be an H-admissible marked graph diagram and let  $D_-$  and  $D_+$  be the diagrams of the lower resolution  $L_-(D)$  and the upper resolution  $L_+(D)$ , respectively. A crossing point p of D is an *lower singular point* (or an *upper singular point*, respectively) if p is an unlinking crossing point of  $D_-$  (or  $D_+$ ).

We introduce new moves for H-admissible marked graph diagrams. They are the moves  $\Gamma_9$ ,  $\Gamma'_9$  and  $\Gamma_{10}$  in Fig. 6, which we call moves of type III. For the moves (a) of  $\Gamma_9$  and  $\Gamma'_9$  in Fig. 6 we require a condition that the components  $l^+$  (in the resolution  $L_+(D)$ ) and  $l^-$  (in the resolution  $L_-(D)$ ) are trivial, respectively. For the moves (b) of  $\Gamma_9$  and  $\Gamma'_9$ , we require a condition that p is an upper singular point and a lower singular point, respectively.

Figure 6: Moves of Type III

**Definition 2.4.** Let D and D' be marked graph diagrams. Marked graph diagrams D and D' are stably equivalent if they are related by a finite sequence of generalized Yoshikawa moves.

**Definition 2.5.** A set S of moves are *independent* if x is not generated by finite sequences of moves in  $S \setminus \{x\}$  for every  $x \in S$ .

**Question 2.6** (S. Kamada, A. Kawauchi, J. Kim, S. Y. Lee [6]). Is the set of generalized Yoshikawa moves independent?

**Lemma 2.7.** Let  $\mathcal{L}$  and  $\mathcal{L}'$  be immersed surface-links, and D and D' their marked graph diagrams, respectively. If D and D' are related by a finite sequence of generalized Yoshikawa moves, then  $\mathcal{L}$  and  $\mathcal{L}'$  are equivalent.

**Problem 2.8** (J. Kim). Find the set S of local moves of marked graph diagrams such that the marked graph diagrams are related by S if and only if their immersed surface-links are equivalent.

**Problem 2.9** (J. Kim). Create a table of H-admissible marked graph diagrams representing immersed surface-links under the equivalence of S in the previous Problem with ch-index 10 or less, where the ch-index of a marked graph diagram is the sum of the number of crossings and that of vertices.

**Definition 2.10** (cf. [5]). A positive (or negative) standard singular 2-knot, denoted by S(+) (or S(-)) is the immersed 2-knot of the marked graph diagram D (or D') in Fig. 7, respectively. An unknotted immersed sphere is defined to be the connected sum mS(+)#nS(-) for any non-negative integers m, n with m + n > 0.

A double point singularity p of an immersed 2-knot S is *inessential* if S is the connected sum of an immersed 2-knot and an unknotted immersed sphere such that p belongs to the unknotted immersed sphere. Otherwise, p is *essential*.

Figure 7: Standard singular 2-knot

### 3 Confirming immersed 2-knots with essential singularity

In this section, the main theorem will be shown with an example of infinitely many immersed 2-knots with essential singularity. For an immersed 2-knot K, let  $E(K) = \operatorname{Cl}(S^4 \setminus \operatorname{N}(K))$ . Let  $\tilde{E}(K)$  be the infinite cyclic covering of E(K). Then the homology  $H(K) = H_1(\tilde{E}(K))$  is a finitely generated  $\Lambda$ -module, where  $\Lambda = \mathbb{Z}[t, t^{-1}]$ . This module is called the *first Alexander module* of K (cf. [15]). Let

 $DH(K) = \{x \in H(K) \mid \exists \{\lambda_i\}_{1 \le i \le m} : \text{coprime } (m \ge 2) \text{ with } \lambda_i x = 0, \forall i\},\$ 

called the annihilator  $\Lambda$ -submodule, which is known to be equal to the integral torsion part of the Alexander module H(K) (cf. [9, Section 3]). Let  $\epsilon(K)$  be the first elementary ideal of DH(K). A  $\Lambda$ -ideal is symmetric if the ideal is unchanged by replacing t by  $t^{-1}$ . Let  $DH(K)^* = \hom(DH(K), \mathbb{Q}/\mathbb{Z})$  have the induced  $\Lambda$ -module structure, called the dual  $\Lambda$ -module of DH(K). The following lemma is used in our argument.

**Lemma 3.1.** If K is a 2-knot such that the dual  $\Lambda$ -module  $DH(K)^*$  is  $\Lambda$ -isomorphic to DH(K), then the first elementary ideal  $\epsilon(K)$  is symmetric.

For any marked graph diagram D of K, the fundamental group  $\pi(K)$  of K is generated by the connected components of D, namely, the connected components obtained from Dby cutting the under-crossing points and the relations  $s_3 = s_2^{-1}s_1s_2$  for all crossings as in (a) or (b) in Fig. 8.

Figure 8: Labels at a crossing or a vertex

A computation of the Alexander module H(K) and the ideal  $\epsilon(K)$  is shown in a concrete example as follows:

**Example 3.2.** Let K be the immersed 2-knot of D in Fig. 9. The immersed 2-knot K has only one double point. The fundamental group  $\pi(K)$  is computed as follows:  $\pi(K) = \langle x_1, x_2, x_3, x_4, x_5, x_6, x_7, x_8, x_9, x_{10}, x_{11}, x_{12}, x_{13}, x_{14}, x_{15} | x_1 = x_2^{-1} x_3 x_2, x_2 = x_3^{-1} x_5 x_3, x_1 = x_3^{-1} x_4 x_3, x_2 = x_1^{-1} x_3 x_1, x_6 = x_2^{-1} x_1 x_2, x_6 = x_1^{-1} x_7 x_1, x_1 = x_7^{-1} x_8 x_7, x_2 = x_7^{-1} x_9 x_7, x_{10} = x_2^{-1} x_7 x_2, x_{10} = x_1^{-1} x_{11} x_1, x_1 = x_1^{-1} x_{12} x_{11}, x_2 = x_{11}^{-1} x_{13} x_{11}, x_{14} = x_2^{-1} x_{11} x_2, x_{14} = x_1^{-1} x_2 x_1, x_1 = x_2^{-1} x_{15} x_2 > .$ 

This group  $\pi(K)$  is isomorphic to the group  $\langle x_1, x_2 | r_1, r_2 \rangle$ , where

$$r_1: x_2x_1x_2^{-1} = x_1x_2x_1^{-1}, \quad r_2: (x_1x_2^{-1})^3x_1(x_1x_2^{-1})^{-3} = x_2.$$

Then the following  $\Lambda$ -semi-exact sequence

$$\Lambda[r_1^*, r_2^*] \stackrel{d_2}{\to} \Lambda[x_1^*, x_2^*] \stackrel{d_1}{\to} \Lambda \stackrel{\varepsilon}{\to} \mathbb{Z} \to 0$$

of the group presentation of  $\pi(K)$  is obtained by using the fundamental formula of the Fox differential calculus in [1], where  $\Lambda[r_1^*, r_2^*]$  and  $\Lambda[x_1^*, x_2^*]$  are free  $\Lambda$ -modules with bases

$$\varepsilon(t) = 1, \ d_1(x_j^*) = t - 1 \ (j = 1, 2), \ d_2(r_i^*) = \sum_{j=1}^u \frac{\partial r_i}{\partial x_j} x_j^* \ (i = 1, 2)$$

for the Fox differential calculus  $\frac{\partial r_i}{\partial x_j}$  regarded as an element of  $\Lambda$  by letting  $x_j$  to t. The Alexander module H(K) is identified with the quotient  $\Lambda$ -module  $\text{Ker}(d_1)/\text{Im}(d_2)$  (see [10, Theorem 7.1.5]). The Alexander matrix  $M_K = (m_{ij})$  defined by  $m_{ij} = \frac{\partial r_i}{\partial x_j}$  is a presentation matrix of the  $\Lambda$ -homomorphism  $d_2$  and calculated as follows:

$$M_K = \left[ \begin{array}{cc} 2t - 1 & 1 - 2t \\ 4 - 3t & 3t - 4 \end{array} \right].$$

Hence we have

$$H(K) \cong \Lambda/(2t - 1, 4 - 3t)$$

which is equal to DH(K). Thus, the first elementary ideal  $\epsilon(K)$  of K is

$$\begin{aligned} \epsilon(K) &= < 2t - 1, 4 - 3t > \\ &= < 2t - 1, 4 - 3t, 3(2t - 1) + 2(4 - 3t) > \\ &= < 2t - 1, 5 > . \end{aligned}$$

The following lemma is useful in a computation for a symmetric ideal.

Lemma 3.3. ([13]) The following statements are equivalent:

- 1. The ideal < 2t 1, m > is symmetric.
- 2. An integer m is  $\pm 2^r$  or  $\pm 2^r 3$  for any integer  $r \ge 0$ .

**Lemma 3.4.** ([13]) There are infinitely many immersed 2-knots with one essential double point singularity.

Let J be one of the immersed 2-knots  $K_n, K'_n(n = 1, 2, 3, ...)$  such that the first elementary ideal  $\epsilon(J)$  is asymmetric. Then the following corollary is obtained.

**Corollary 3.5.** The connected sum J#U of J and any immersed 2-knot U such that the group orders |DH(J)| and |DH(U)| are coprime is an immersed 2-knot with at least one essential double point singularity.

Finally, the ideal (2t - 1, 5) is known to be the first elementary ideal of a ribbon torus-knot in [4].

By using an immersed 2-knot in Lemma 3.4, the following main theorem is proved.

**Theorem 3.6.** ([13]) Let  $K = nK_m^*$  be the connected sum of n copies of an immersed 2-knot  $K_m^*$  with one essential double point singularity whose first elementary ideal is < 2t - 1, m > for any integer  $m \ge 5$  without factors 2 and 3. Then K gives infinitely many immersed 2-knots with n double point singularities every of which is essential.
