RIMS Workshop on

**Mathematical Analysis of Viscous Incompressible Fluid**

Date: December 6 (Mon) – 8 (Wed), 2021  
Venue: Online via Zoom  
Organizers: Yasunori Maekawa (Kyoto University)  
Yoshihiro Shibata (Waseda University)

This workshop will be held online via Zoom.  
To participate in the workshop please register from the following form.

https://forms.gle/JgNuiBvyJeqGqYUu7

Deadline for registration: December 3 (Fri), 2020
Zoom URL information will be sent by email to all registrants on December 4 (Sat).

**Program**

**Monday, December 6**

14:00 · 14:50  Koji Ohkitani (Kyoto University)  
Self-similar profiles of solutions to hypo-viscous fluid equations

15:05 · 15:55  Hirokazu Saito (The University of Electro-Communications)  
On the two-phase Navier-Stokes equations with a sharp interface

16:10 · 16:40  Ryosuke Nakasato (Tohoku University)  
Well-posedness for the magnetohydrodynamics with Hall-effect near non-zero magnetic equilibrium states

16:50 · 17:20  Zhongyang Gu (The University of Tokyo)  
The Helmholtz decomposition of a space of vector fields with bounded mean oscillation in a bounded domain
Tuesday, December 7

10:00 · 10:50 Tai-Peng Tsai (The University of British Columbia)
Weak and mild solutions to the Navier-Stokes equations in Wiener amalgam spaces

11:05 · 11:55 Ken Abe (Osaka City University)
Rigidity of Beltrami fields with a non-constant proportionality factor

14:00 · 14:50 Jan Brezina (Kyushu University)
On barotropic Navier-Stokes system with general boundary conditions

15:05 · 15:55 Erika Ushikoshi (Yokohama National University / Osaka University)
Hadamard variational formula for the fundamental solution of the non stationary Stokes equations

16:10 · 16:40 Tatsu-hiko Miura (Kyoto University)
Enhanced dissipation for the two-jet Kolmogorov type flow on the unit sphere

Wednesday, December 8

10:00 · 10:50 Yoshifumi Kimura (Nagoya University)
Vortex reconnection and a finite-time singularity of the Navier-Stokes equations

11:05 · 11:55 Ryo Takada (Kyushu University)
Fast rotation limit for the incompressible Navier-Stokes equations in a 3D layer
RIMS workshop
「Mathematical Analysis of Viscous Incompressible Fluid」
December, 6-8, 2021 (Online via Zoom)
Organizers: Yasunori Maekawa (Kyoto University)
Yoshihiro Shibata (Waseda University)

Abstracts
Self-similar profiles of solutions to hypo-viscous fluid equations
Koji Ohkitani
Research Institute for Mathematical Sciences, Kyoto University
ohkitani@kurims.kyoto-u.ac.jp

1 Motivation
We consider the source-type solution to the hypoviscous Burgers equation and provide a heuristic argument for finding a “Cole-Hopf-like transform” for its possible linearisation.

2 Burgers equation with standard dissipativity (review)
We consider the Burgers equation
\[ u_t + uu_x = \nu u_{xx}, \tag{1} \]
which satisfies static scale-invariance under \( x \to \lambda x, t \to \lambda^2 t, u \to \lambda^{-1} u, \) for any \( \lambda(>0). \)
This means that if \( u(x,t) \) is a solution, so is \( u_\lambda(x,t) := \lambda u(\lambda x, \lambda^2 t). \) E.g. it is readily checked that \( \|u_\lambda\|_{L^p} = \lambda^{\frac{p-1}{p}} \|u\|_{L^p} \), which shows that the \( L^1 \)-norm is scale-invariant.

Let us clarify the two kinds of critical scale-invariance.
Type 1 critical scale-invariance is achieved with the velocity potential \( \phi, \) defined by \( u = \phi_x, \) which obeys
\[ \phi_t + \frac{1}{2} \phi_x^2 = \nu \phi_{xx}, \tag{2} \]
where \([\phi] = [\nu] = L^2/T.\) If \( \phi(x,t) \) is a solution, so is \( \phi(\lambda x, \lambda^2 t). \) Under dynamic scaling for the velocity potential \( \phi(x,t) = \Phi(\xi, \tau), \) \( \xi = \frac{x}{\sqrt{2at}}, \tau = \frac{t}{2a} \log t, (a > 0) \) we have
\[ \Phi_\tau + \frac{1}{2} \Phi_{\xi}^2 = \nu \Phi_{\xi\xi} + a \xi \Phi_\xi. \tag{3} \]
Type 1 critical scale-invariance is deterministic in nature, where the number of additional terms is minimised, that is, only the drift term.

The other type 2 critical scale-invariance concerns the \( n \)th spatial derivative of the unknown for the type 1 scale-invariance (\( n \) is the spatial dimension.) For the Burgers equation, under dynamic scaling for velocity \( u(x,t) = \frac{1}{\sqrt{2at}} U(\xi, \tau), \) we find
\[ U_\tau + \frac{1}{2} \Phi_{\xi}^2 + \nu U_{\xi\xi} + a \xi U_\xi, \tag{4} \]
whose linearisation is the Fokker-Planck equation. The type 2 scale-invariance is statistical in nature where the number of additional terms is maximised in the sense that a divergence form is completed with the addition of \( aU \) term. A steady solution to (4) is known as the source-type solution where \( C = C(M) \) is a constant, see e.g. \[1, 2].\) Observe that (5) is a near-identity transformation of the Gaussian function.

\[ U(\xi) = \frac{C \exp\left(-\frac{\xi^2}{2\nu}\right)}{1 - \frac{C}{2\nu} \int_0^\xi \exp\left(-\frac{\eta^2}{2\nu}\right) d\eta}. \tag{5} \]
3 Burgers equation with hypo-viscous dissipativity

We now turn our attention to the hypo-viscous Burgers equation of the following form

\[ u_t + uu_x = -\nu' \Lambda u, \tag{6} \]

where \( \Lambda \equiv (-\partial_{xx})^{1/2} = \partial_x H[\cdot] \) denotes the Zygmund operator and \( H[\cdot] \) the Hilbert transform. The equation is known to be well-posed [3]. We are interested in deriving a source-type solution analogous to (5).

**Type 1 critical scale-invariance:** under dynamic scaling \( u(x, t) = U(\xi(t)) \), \( \xi(t) = x/a \log t \), \( \tau = \frac{1}{a} \log t \), where \( [\nu'] = [u] = L/T \), (6) is transformed to

\[ U_t + UU_\xi = -\nu' \Lambda U + a\xi U_\xi. \tag{7} \]

**Type 2 critical scale-invariance:** the governing equation for velocity gradient \( w = u_x \)

\[ w_t + uw_x = -w^2 - \nu' \Lambda w, \]

is transformed under dynamic scaling to

\[ W_\tau + UW_\xi = -W^2 - \nu' \Lambda W + a(\xi W)_\xi, \tag{8} \]

where \( W = U_\xi \). Note that the difference in dissipativity offsets the pair of critical variables (\( U, W \)) by one derivative from that of the standard Burgers equation’s (\( \Phi, U \)).

**Self-similar profile:** late-time behaviour is determined by the self-similar profile \( W(\xi) = \lim_{\tau \to \infty} W(\xi, \tau) \), if it exists. Its equation is obtained by setting \( W_\tau = 0 \) in (8)

\[ (UW)_\xi = -\nu' \Lambda W + a(\xi W)_\xi, \]

which is integrated to give

\[ \frac{1}{\mu} \xi W - H[W] = \frac{1}{\nu'} UW, \tag{9} \]

where \( \mu = \nu'/a \). This is the equation we ought to solve. It is clear that \( W = \frac{\mu}{\xi^2 + \mu^2} \) and \( H[W] = \frac{\xi}{\xi^2 + \mu^2} \) solves it, when the nonlinearity (that is, RHS) is discarded. We will handle (9) perturbatively assuming that the nonlinearity is small. A numerical approach for handling (8) will also discussed. Time permitting, the SQG equation will also be addressed together with comparisons to other works.

On the two-phase Navier-Stokes equations with a shape interface

Hirokazu Saito
The University of Electro-Communications
hsaito@uec.ac.jp

Let $\Omega_{\pm}(t)$ and $\Gamma(t)$, $t > 0$, be given by

$$\Omega_{\pm}(t) = \{ x = (x', x_3) \in \mathbb{R}^3 : x' = (x_1, x_2) \in \mathbb{R}^2, \pm(x_3 - \eta(x', t)) > 0 \}$$

$$\Gamma(t) = \{ x = (x', x_3) \in \mathbb{R}^3 : x' = (x_1, x_2) \in \mathbb{R}^2, x_3 = \eta(x', t) \}.$$

In this talk, we consider the motion of two immiscible, viscous, incompressible fluids, $\text{fluid}_+$ and $\text{fluid}_-$, which occupy $\Omega_+(t)$ and $\Omega_-(t)$, respectively. The positive constants $\rho_\pm$ and $\mu_\pm$ denote the densities and the viscosity coefficients of the respective fluids. Define $\rho = \rho_+ \mathbb{I}_{\Omega_+(t)} + \rho_- \mathbb{I}_{\Omega_-(t)}$ and $\mu = \mu_+ \mathbb{I}_{\Omega_+(t)} + \mu_- \mathbb{I}_{\Omega_-(t)}$, where $\mathbb{I}_A$ is the indicator function of $A \subset \mathbb{R}^3$.

Let $\mathbf{v} = (v_1(x, t), v_2(x, t), v_3(x, t))^T$ be the fluid velocity and $q = q(x, t)$ the pressure at position $x \in \Omega_+(t) \cup \Omega_-(t)$ with time $t > 0$. The motion is governed by the two-phase Navier-Stokes equations with the sharp interface $\Gamma(t)$ as follows:

$$\frac{\partial \eta}{\partial t} - v_3 = -\mathbf{v}' \cdot \nabla \eta \quad \text{on} \ \Gamma(t),$$

$$\rho(\partial_t \mathbf{v} + (\mathbf{v} \cdot \nabla) \mathbf{v}) = \mu \Delta \mathbf{v} - \nabla q \quad \text{in} \ \Omega_+(t) \cup \Omega_-(t),$$

$$\text{div} \ \mathbf{v} = 0 \quad \text{in} \ \Omega_+(t) \cup \Omega_-(t);$$

the boundary conditions

$$-[(\mu \mathbf{D}(\mathbf{v}) - q \mathbb{I}) \mathbf{n}_{\Gamma(t)}] - [\rho] \gamma_a \eta \mathbf{n}_{\Gamma(t)} = \sigma \kappa_{\Gamma(t)} \mathbf{n}_{\Gamma(t)} \quad \text{on} \ \Gamma(t),$$

$$\{\mathbf{v}\} = 0 \quad \text{on} \ \Gamma(t);$$

the initial conditions

$$\eta \big|_{t=0} = \eta_0 \quad \text{on} \ \mathbb{R}^2, \quad \mathbf{v} \big|_{t=0} = \mathbf{v}_0 \quad \text{in} \ \Omega_0^+ \cup \Omega_0^-.$$
Define the extension operators $E_{\pm}$ by $E_{\pm}\eta = \int_{R^2} e^{i\xi \cdot x} f(x') dx'$ and $F_{\pm}(\xi') = (2\pi)^{-2} \int_{R^2} e^{i\xi \cdot x} g(\xi') dx'$. Let $\Theta_{\pm}$ be diffeomorphisms such that

$$\Theta_{\pm} : R^3_+ \times (0, \infty) \ni (x, t) \mapsto (x', x_3, t) \in \bigcup_{\tau \in (0, \infty)} \Omega_{\pm} (\tau) \times \{\tau\},$$

where $R^3_+ = \{x_3 > 0\}$. One sets $u_{\pm} = u(x, t, \nu(\Theta_{\pm}(x, t)))$ and $p_{\pm} = p(x, t) = q(\Theta_{\pm}(x, t))$, and then (1) becomes

$$\begin{cases}
\partial_t \eta - u_\cdot e_3 = D(\eta, u_\cdot) & \text{on } R^3_0 \times (0, \infty),
\rho_\pm \partial_t u_\pm - \mu_\pm \Delta u_\pm + \nabla p_\pm = F_\pm(\eta, u_\pm) & \text{in } R^3_\pm \times (0, \infty),
\text{div } u_\pm = G_\pm(\eta, u_\pm) = \text{div } \tilde{G}_\pm(\eta, u_\pm) & \text{in } R^3_\pm \times (0, \infty),
\end{cases}
\tag{4}$$

where $R^3_0 = \{x_3 = 0\}$; the boundary conditions in (2) become

$$\begin{cases}
-(\mu_+ D(u_+) - p_+) e_3 - (\mu_- D(u_-) - p_-) e_3 = -(\rho_+ - \rho_-) \gamma_\eta e_3 - \sigma \Delta' e_3
= H_+(\eta, u_+) - H_-(\eta, u_-) + \sigma H_\gamma(\eta) e_3 & \text{on } R^3_0 \times (0, \infty),
\end{cases}
\tag{5}$$

where $e_3 = (0, 0, 1)^T$ and $\Delta' = \sum_{j=1}^2 \partial_j^2 \eta$; the initial conditions in (3) become

$$\begin{array}{ll}
\eta|_{t=0} = \eta_0 & \text{on } R^2, \\
u_\pm|_{t=0} = u_{0\pm} & \text{in } R^3_\pm.
\end{array}
\tag{6}$$

Here $D(\eta, u_\cdot)$, $F_\pm(\eta, u_\pm)$, $G_\pm(\eta, u_\pm)$, $H_\pm(\eta, u_\pm)$, and $H_\gamma(\eta)$ are nonlinear terms. Our main result then reads as follows.

**Theorem 1.** Suppose $\rho_- > \rho_+$. Then there exist a large number $p_0 > 2$ and small positive numbers $q_0$, $r_0$, $\varepsilon_0$ such that for any $p$, $q_1$, and $q_2$ satisfying

$$p_0 \leq p < \infty, \quad 2 < q_1 \leq 2 + q_0, \quad 3 < q_2 < \infty,$$

and for any

$$(\eta_0, u_{0+}, u_{0-}) \in \bigcap_{r \in (q_1/2, q_2)} B^{3-1/p-1/r}(R^2) \times B^{2-2/p-2/q}(R^3_+) \times B^{2-2/p-2/q}(R^3_-),$$

satisfying some compatibility condition and the smallness condition

$$\sum_{r \in (q_1/2, q_2)} ||(\eta, u_{0+}, u_{0-})||_{B^{3-1/p-1/r}(R^2) \times B^{2-2/p-2/q}(R^3_+) \times B^{2-2/p-2/q}(R^3_-)} \leq \varepsilon_0,$$

(4)–(6) admits a unique solution $(\eta, u_+, u_-)$, with pressures $p_{\pm}$, satisfying

$$\sum_{q \in (q_1, q_2)} \left( ||(t)^{1/2}(\eta, u_{0+}, u_{0-})||_{L^p(R^+_3 \times W^{3-1/q}_q(R^2) \times H^2_\theta(R^3_+)^3 \times H^2_\theta(R^3_-)^3)} + ||(t)^{1/2}(\partial_\eta u_+, \partial_\eta u_-)||_{L^p(R^+_3 \times W^{2-1/q}_q(R^2) \times L^q(R^3_+)^3 \times L^q(R^3_-)^3)} \right) \leq r_0.$$

Here $(t) = \sqrt{1+t^2}$ and the compatibility condition is introduced in the talk.
Well-posedness for the magnetohydrodynamics with Hall-effect near non-zero magnetic equilibrium states

Ryosuke Nakasato
Graduate school of Science, Tohoku University
ryosuke.nakasato.e4@tohoku.ac.jp

We consider the initial-value problem for the incompressible magnetohydrodynamic system with the Hall-effect (we also call it the Hall-magnetohydrodynamic system) in the 3-dimensional Euclidean space \( \mathbb{R}^3 \):

\[
\begin{align*}
\partial_t u - \Delta u + (u \cdot \nabla) u + \nabla p &= (\nabla \times \vec{B}) \times \vec{B}, \quad t > 0, x \in \mathbb{R}^3, \\
\partial_t \vec{B} - \Delta \vec{B} + \nabla \times (\nabla \times \vec{B}) &= \vec{B} \times (u \times \vec{B}), \quad t > 0, x \in \mathbb{R}^3, \\
\nabla \cdot u &= \nabla \cdot \vec{B} = 0, \quad t > 0, x \in \mathbb{R}^3, \\
(u, \vec{B})|_{t=0} &= (u_0, \vec{B}_0),
\end{align*}
\]

where \( u = u(t, x) : \mathbb{R}_+ \times \mathbb{R}^3 \to \mathbb{R}^3 \), \( p = p(t, x) : \mathbb{R}_+ \times \mathbb{R}^3 \to \mathbb{R} \) and \( \vec{B} = \vec{B}(t, x) : \mathbb{R}_+ \times \mathbb{R}^3 \to \mathbb{R}^3 \) denote the velocity of the fluid, the pressure and the magnetic field, respectively. The third term of the second equations is often called the Hall-term. The system (1) is used to model the magnetic reconnection phenomenon, that is not able to be explained by the well-known magnetohydrodynamic system (namely, the system (1) without the Hall-term).

The aim of this talk is to obtain a solution as a perturbation from a constant equilibrium state \((0, \vec{B})\), where \( \vec{B} \in \mathbb{R}^3 \). In the case \( \vec{B} = 0 \), Danchin–Tan [1] have obtained a global-in-time solution of (1) in critical Besov spaces.

Under the assumption \( \vec{B} \neq 0 \), let us reformulate the system (1) by introducing the new unknown vector-valued function \( B := \vec{B} - \vec{B} \) to get the following initial-value problem:

\[
\begin{align*}
\partial_t u - \Delta u + \nabla \left( p + \frac{|B|^2}{2} \right) - (\nabla \times B) \times \vec{B} &= F, \quad t > 0, x \in \mathbb{R}^3, \\
\partial_t B - \Delta B + \nabla \times \left( (\nabla \times B) \times \vec{B} \right) - \nabla \times (u \times \vec{B}) &= \nabla \times G, \quad t > 0, x \in \mathbb{R}^3, \\
\nabla \cdot u &= \nabla \cdot B = 0, \quad t > 0, x \in \mathbb{R}^3, \\
(u, B)|_{t=0} &= (u_0, B_0),
\end{align*}
\]

where the nonlinear terms \( F, G \) are given by

\[
F := -(u \cdot \nabla) u + (B \cdot \nabla) B, \quad G := u \times B - (\nabla \times B) \times B,
\]

respectively. In this talk, we shall state the results on the global well-posedness for the system (2) in a critical \( L^p \)-framework corresponding to Danchin–Tan [1].

The Helmholtz decomposition of a space of vector fields with bounded mean oscillation in a bounded domain

Zhongyang Gu
Yoshikazu Giga
The University of Tokyo
zgu@ms.u-tokyo.ac.jp

The Helmholtz decomposition of a vector field is a fundamental tool to analyse the Stokes and the Navier-Stokes equations. It is formally a decomposition of a vector field $v$ in a domain $\Omega$ of $\mathbb{R}^n$ into

$$ v = v_0 + \nabla q $$

where $v_0$ is a divergence free vector field with supplemental condition like the boundary condition and $\nabla q$ denotes the gradient of a scalar field $q$. If $v$ is in $L^p$ in $\Omega$ for $1 < p < \infty$, such a decomposition is well-studied; see e.g. [1]. However, if the vector field is of bounded mean oscillation (BMO for short), such a problem is only studied when $\Omega$ is a half space $\mathbb{R}^n_+$ [2], where the boundary is flat. The goal of our result is to establish the Helmholtz decomposition of BMO vector fields in a bounded domain, which is a typical example of a domain with curved boundary.

Although the space of BMO functions in $\mathbb{R}^n$ is well-studied, the situation is less clear if we consider such a space in a domain since there are several possible definitions due to the presence of the boundary $\partial \Omega$. Here is our setting. Let $\Omega$ be a bounded $C^3$ domain. Let $\mu \in (0, \infty]$, for $f \in L^1_{\text{loc}}(\Omega)$ we define

$$ [f]_{BMO^\mu(\Omega)} := \sup \left\{ \frac{1}{|B_r(x)|} \int_{B_r(x)} |f(y) - f_{B_r(x)}| \, dy \bigg| B_r(x) \subset \Omega, r < \mu \right\} $$

where

$$ f_{B_r(x)} := \frac{1}{|B_r(x)|} \int_{B_r(x)} f(y) \, dy. $$

Then we define the space $BMO^\mu(\Omega)$ as

$$ BMO^\mu(\Omega) := \{ f \in L^1_{\text{loc}}(\Omega) \mid [f]_{BMO^\mu(\Omega)} < \infty \}. $$

For $\nu \in (0, \infty]$, we set

$$ [f]_{b^\nu} := \sup \left\{ r^{-n} \int_{B_r(x) \cap \Omega} |f(y)| \, dy \bigg| x \in \partial \Omega, 0 < r < \nu \right\} $$

and let $d_\Omega(x)$ denote the distance of $x$ from the boundary $\partial \Omega$, i.e.,

$$ d_\Omega(x) = \inf \{|x - y|, y \in \partial \Omega\}. $$
We then define the space
\[ v_{BMO}^{\mu,\nu}(\Omega) = \{ v \in (BMO^\mu(\Omega))^n \mid [\nabla d_\Omega \cdot v]_{\nu} < \infty \} \]
where for \( v \in v_{BMO}^{\mu,\nu}(\Omega) \),
\[ [v]_{v_{BMO}^{\mu,\nu}(\Omega)} := [v]_{BMO^\mu(\Omega)} + [\nabla d_\Omega \cdot v]_{\nu}. \]
This space is introduced in our companion paper [3] in which the seminorm \([\cdot]_{v_{BMO}^{\mu,\nu}(\Omega)}\) is shown to be equivalent as far as each index is finite. In particular, in the case for a bounded domain, \([\cdot]_{v_{BMO}^{\mu,\nu}(\Omega)}\) is indeed a norm and the space \(v_{BMO}^{\mu,\nu}(\Omega)\) is a Banach space. Moreover, this space is independent of \(\mu, \nu\) including \(\infty\). Hence, when \(\Omega\) is bounded, without loss of generality we denote \(v_{BMO}^{\mu,\nu}(\Omega)\) by \(v_{BMO}(\Omega)\). The main theorem of our research reads as follow.

**Theorem 1.** Let \(\Omega\) be a bounded \(C^3\) domain in \(\mathbb{R}^n\). Then the topological direct sum decomposition
\[ v_{BMO}(\Omega) = v_{BMO_\sigma}(\Omega) \oplus Gv_{BMO}(\Omega) \]
holds with
\[ v_{BMO_\sigma}(\Omega) := \{ v \in v_{BMO}(\Omega) \mid \text{div } v = 0 \text{ in } \Omega, v \cdot n = 0 \text{ on } \partial \Omega \}, \]
\[ Gv_{BMO}(\Omega) := \{ \nabla q \in v_{BMO}(\Omega) \mid q \in L^1_{\text{loc}}(\Omega) \} \]
where \(n\) denotes the exterior unit normal vector field. In other words, for \(v \in v_{BMO}(\Omega)\), there exist unique \(v_0 \in v_{BMO_\sigma}(\Omega)\) and \(\nabla q \in Gv_{BMO}(\Omega)\) satisfying \(v = v_0 + \nabla q\). Moreover, the mappings \(v \mapsto v_0\) and \(v \mapsto \nabla q\) are bounded in \(v_{BMO}(\Omega)\).

For the space \(v_{BMO}(\Omega)\) that we consider, it is essential that we only require the normal component of \(v\), i.e., \(\nabla d_\Omega \cdot v\), to be \(b^\nu\) bounded in order to have the Helmholtz decomposition. Requiring every component \(v_i\) of \(v\) to be \(b^\nu\) bounded is too strict to have the Helmholtz decomposition.

Weak and mild solutions to the Navier-Stokes equations in Wiener amalgam spaces

Tai-Peng Tsai
University of British Columbia
ttsai@math.ubc.ca

For the three dimensional incompressible Navier-Stokes equations in the \( L^p \) setting, the classical theories give existence of weak solutions for data in \( L^2 \) and mild solutions for data in \( L^p, p \geq 3 \). These were extended to \( L^p_{uloc} \) spaces, the space of functions with uniform local \( L^p \) norms, by Lemarié-Rieusset for weak solutions, and by Maekawa and Terasawa for mild solutions. Our goal is to build existence theorems in intermediate spaces that bridge \( L^p \) and \( L^p_{uloc} \).

The Wiener amalgam space \( E(p, q) \) consists of functions whose local \( L^p \)-norms at lattice points are globally in \( \ell^q \). Thus a function in \( E(p, q) \) has local integrability in \( L^p \) and global decay in \( \ell^q \).

For weak solutions, we establish global existence in \( E(2, q) \) for \( q \) between 2 and \( \infty \). For \( q \) close to 2, the solutions are shown to satisfy some properties known in the Leray class but not the Lemarié-Rieusset class, namely eventual regularity and long time estimates on the growth of the local energy.

For mild solutions, we establish local existence in \( E(p, q) \) for \( p \in (3, \infty] \) and \( q \in [2, \infty] \). When \( p = 3 \), a further smallness assumption on the initial data ensures local existence if \( q > 3 \), and global existence if \( q \leq 3 \). We also prove local spacetime integral bounds of the solutions using Giga’s estimates.

This talk is based on joint work with Zachary Bradshaw and Chen-Chih Lai.

Rigidity of Beltrami fields with a non-constant proportionality factor

Ken Abe
Osaka City University
kabe@osaka-cu.ac.jp

Beltrami fields \( \text{curl } u = fu \), \( \text{div } u = 0 \) appear as steady states of ideal incompressible flows or plasma equilibria. I will discuss existence and non-existence issues on them for non-constant factor \( f \). In the first half of the talk, I will explain existence of axisymmetric Beltrami fields forming vortex rings and their construction via a variational principle. In the second half, I will discuss a rigidity problem on symmetry of \( u \) for symmetric \( f \) and a relation with Grad’s conjecture. This talk is based on preprints \texttt{arXiv:2008.09345}, \texttt{arXiv:2108.03870}. 

On barotropic Navier-Stokes system with general boundary conditions

Jan Březina
Kyushu University
brezina@artsci.kyushu-u.ac.jp

We consider the barotropic Navier–Stokes system describing the motion of a compressible Newtonian fluid in a bounded domain with in and out flux boundary conditions. That is, the time evolution of the mass density \( \rho = \rho(t, x) \) and the velocity \( u = u(t, x) \) is governed by

\[
\begin{align*}
\partial_t \rho + \text{div}_x (\rho u) &= 0, \\
\partial_t (\rho u) + \text{div}_x (\rho u \otimes u) + \nabla_x p &= \text{div}_x S(D_x u) + \rho \nabla_x G,
\end{align*}
\]

where \( S(D_x u) = \mu \left( \nabla_x u + \nabla_x^T u - \frac{2}{d} \text{div}_x u I \right) + \lambda \text{div}_x u I, \quad \mu > 0, \quad \lambda \geq 0, \) and \( D_x u \equiv \frac{1}{2} \left( \nabla_x u + \nabla_x^T u \right), \)

(1)
on a bounded domain \( \Omega \subset \mathbb{R}^d, \ d = 1, 2, 3 \) and we consider the realistic situation with a given boundary velocity,

\[ u|_{\partial \Omega} = u_b, \]

(2)and, decomposing the boundary as

\[ \partial \Omega = \Gamma_{\text{in}} \cup \Gamma_{\text{out}}, \quad \Gamma_{\text{in}} = \left\{ x \in \partial \Omega \mid \text{the outer normal } n(x) \text{ exists, and } u_b(x) \cdot n(x) < 0 \right\}, \]

we prescribe the density on the in–flow component,

\[ \rho|_{\Gamma_{\text{in}}} = \rho_b. \]

(3)Note that \( \Gamma_{\text{out}} \) includes the part of the boundary on which the field \( u_b \) is tangential, meaning \( u_b \cdot n = 0. \)

We show that if the boundary velocity coincides with that of a rigid motion, all solutions converge to an equilibrium state for large times. In other words, we study stability and convergence to the static states in the multi–dimensional case, with the velocity \( u_E \) associated to a rigid motion, meaning

\[ D_x u_E = 0. \]

(4)The corresponding density \( \rho_E \) satisfies

\[
\begin{align*}
\text{div}_x (\rho_E u_E) &= 0, \\
\text{div}_x (\rho_E u_E \otimes u_E) + \nabla_x p &= \rho_E \nabla_x G.
\end{align*}
\]

(5)
Accordingly, we consider the problem (1)–(3) with the boundary conditions

\[ u_b = u_E \text{ on } \partial \Omega, \quad \varrho_b = \varrho_E \text{ on } \Gamma_{in}. \]  

Under the hypothesis (6), and if the stationary density \( \varrho_E \) is strictly positive, the problem (1)–(3) admits a Lyapunov function, namely the relative energy

\[ \int_{\Omega} E \left( \varrho, u \bigg| \varrho_E, u_E \right), \quad E \left( \varrho, u \bigg| \varrho_E, u_E \right) \equiv \left[ \frac{1}{2} |u - u_E|^2 + P(\varrho) - P'(\varrho_E)(\varrho - \varrho_E) - P(\varrho_E) \right]. \]

The situation becomes more delicate if \( \varrho_E \) vanishes on a non–trivial part of \( \Omega \). In that case, the stationary problem may admit more (infinitely many) solutions even if the total mass is prescribed.

Our main result asserts that any weak solution of the problem (1)–(3), satisfying a suitable form of energy inequality, approaches the equilibrium solution \([\varrho_E, u_E]\) as \( t \to \infty \) as long as the stationary problem (5) admits a unique solution. To the best of our knowledge, this is the first result of this kind in the multi–dimensional case under the non–zero in/out flow boundary conditions. Note that such a result does not follow from “standard” arguments, even if \( \varrho_E > 0 \), as the Lyapunov function

\[ t \mapsto \int_{\Omega} E \left( \varrho, u \bigg| \varrho_E, u_E \right) (t, \cdot) \]

is not continuous on the trajectories generated by weak solutions.
Hadamard variational formula for the fundamental solution
of the nonstationary Stokes equations
Erika Ushikoshi
Yokohama National University & Osaka University
ushikoshi-erika-ng@ynu.ac.jp

1 Introduction

Let \( \Omega \subset \mathbb{R}^3 \) be a bounded domain with a smooth boundary \( \partial \Omega \). We consider the
nonstationary Stokes equations with the Dirichlet boundary conditions in \( \Omega \);

\[
\begin{aligned}
\frac{dv}{dt}(x, t) - \Delta_x v(x, t) + \nabla_x p(x, t) &= f(x, t), \quad x \in \Omega, \ t > 0, \\
\text{div}_x v(x, t) &= 0, \quad x \in \Omega, \ t > 0, \\
v(x, t) &= 0, \quad x \in \partial \Omega, \ t > 0, \\
v(x, 0) &= a_0(x),
\end{aligned}
\]

(1)

where \( v(x, t) = (v^1(x, t), v^2(x, t), v^3(x, t)) \) and \( p(x, t) \) denote unknown velocity and pressure, respectively. Furthermore, \( f(x) = (f^1(x), f^2(x), f^3(x)) \) is a given external force and \( a(x) = (a^1(x), a^2(x), a^3(x)) \) is an initial data. It is known that the solution of (1)
can be expressed by

\[
v^m(x, t) = \int_{\Omega} a_0(y) \cdot U_m(y - x, t) \, dy + \int_0^t \int_{\Omega} f(x, \tau) \cdot U_m(y - x, t - \tau) \, dyd\tau, \quad m = 1, 2, 3
\]

for a given \( f \) and \( a_0 \), where \( U_m(x, t) \) is the fundamental solution for that.

The purpose of this article is to analyze the domain dependence of \( U_m(x, t) \). Such a
problem was firstly considered in Hadamard [1] for the Green function of the Laplace
equation, and in recent years, Kozono-Ushikoshi [2] and Ushikoshi [5] investigated that
for the stationary Stokes equations. On the other hand, Ozawa [3] presented the variational
formula for the fundamental solution of the heat equation, which was applied to
determine the topological type of the domain by the variation of the eigenvalues for the
Laplace operator in Ozawa [4]. We establish the Hadamard variational formula for the
fundamental solution of the nonstationary Stokes equations with the Dirichlet boundary
conditions. This is the joint work with Mr. Masaru Kamiya who is a graduate of
Yokohama National University.

2 Main Result

We assume that for every \( \varepsilon \geq 0 \), there is a diffeomorphism \( \Phi_\varepsilon : \Omega \to \Omega_\varepsilon \) satisfying the
following conditions.

\[
\Phi_\varepsilon = (\phi_1^\varepsilon, \phi_2^\varepsilon, \phi_3^\varepsilon) \in C^\infty(\overline{\Omega})^3.
\]
(A.2) $\Phi_0(x) = x$ for all $x \in \Omega$.

(A.3) There exists $S = (S^1, S^2, S^3) \in C^\infty(\overline{\Omega})^3$ such that $K(x; \varepsilon) := \Phi_\varepsilon(x) - x - S(x)\varepsilon$ satisfies $\sup_{x \in \Omega} |K(x; \varepsilon)| + \sup_{x \in \Omega} |\nabla K(x; \varepsilon)| = O(\varepsilon^2)$ as $\varepsilon \to 0$.

(A.4) It holds that
\[
\det \left( \frac{\partial \phi_i^j(x)}{\partial x^j} \right)_{i,j = 1, 2, 3} = 1 \quad \text{for all} \quad x \in \overline{\Omega} \quad \text{and all} \quad \varepsilon \geq 0.
\]

For the fundamental solution $U_{\varepsilon, m}(x, t)$ of (1) in $\Omega_{\varepsilon} \times (0, T)$, the following theorem holds;

Theorem 1. Let $\{U_{\varepsilon, m}\}_{m = 1, 2, 3}$ be the fundamental solution of (1) in $\Omega_{\varepsilon} \times (0, T)$. Then for any $y, z \in \Omega$ with $y \neq z$, there exists
\[
\delta U^k_m(y, z, t) := \lim_{\varepsilon \to 0} \frac{U^k_{\varepsilon, m}(y, z, t) - U^k_m(y, z, t)}{\varepsilon}
\]
for all $t > 0$. Moreover, it is expressed by
\[
\delta U^k_m(y, z, t) = \int_0^t \int_{\Omega} S(x) \cdot \nu_x \sum_{i=1}^3 \left( \frac{\partial U^i_{\varepsilon, m}(x, z, \tau)}{\partial x^i} \frac{\partial U^k_{\varepsilon, m}(x, y, t - \tau)}{\partial x^k} \right) d\sigma_x d\tau
\]
for $k, m = 1, 2, 3$, where $S$ is as in (A.3), $\nu_x = (\nu_x^1, \nu_x^2, \nu_x^3)$ is the unit outer normal to $\partial \Omega$ at $x \in \partial \Omega$ and $d\sigma_x$ denotes the surface element of $\partial \Omega$.

Remark 1. We assume that the domain is smoothly perturbed with keeping its volume. In order to remove this assumption, we need to simplify the method to construct its formula and make use of the piola transform.

The key lemma is as follows.

Lemma 2.1. Let $\{V_{\varepsilon, m}\}_{m = 1, 2, 3}$ be the function defined in $\Omega_T := \Omega \times (0, T)$ by
\[
V^k_{\varepsilon, m}(x, y, t) := \sum_{j=1}^3 \frac{\partial x^j_{\varepsilon, m}(x)}{\partial x^j} U^{j}_{\varepsilon, m}(\Phi_\varepsilon(x), \Phi_\varepsilon(y), t), \quad k = 1, 2, 3.
\]
Then, for any $0 < \theta < 1$ and for any $y \in \Omega$, it holds that
\[
\|(V_{\varepsilon, m} - U_m)(\cdot - y, \cdot)\|_{C^{2+\theta, \frac{5}{2}}(\Omega_T)}^2 \to 0 \quad \text{as} \quad \varepsilon \to 0
\]
for $m = 1, 2, 3$, where $\{U_m\}_{m = 1, 2, 3}$ is the fundamental solution of (1) in $\Omega_T$ and $\|\cdot\|_{C^{2+\theta, \frac{5}{2}}(\Omega_T)}$ denotes the norm of $C^{2+\theta, \frac{5}{2}}(\Omega_T)$.

Enhanced dissipation for the two-jet Kolmogorov type flow on the unit sphere

Tatsu-Hiko Miura
Department of Mathematics, Kyoto University
t.miura@math.kyoto-u.ac.jp

A part of this talk is based on a joint work with Professor Yasunori Maekawa.

We consider the vorticity equation for a viscous fluid on the 2D unit sphere \( S^2 \) in \( \mathbb{R}^3 \) of the form

\[
\partial_t \omega + \mathbf{u} \cdot \nabla \omega - \nu(\Delta \omega + 2\omega) = f, \quad \mathbf{u} = \mathbf{n}_{S^2} \times \nabla \Delta^{-1} \omega \quad \text{on} \quad S^2 \times (0, \infty). \tag{1}
\]

Here \( \omega \) is the scalar vorticity, \( \mathbf{u} \) is the tangential velocity field, and \( f \) is a given external force. Also, \( \nu > 0 \) is the viscosity coefficient, \( \nabla \) is the gradient on \( S^2 \), \( \Delta \) is the Laplace–Beltrami operator on \( S^2 \) which is invertible on the space \( L^2_0(S^2) \) of \( L^2 \) functions on \( S^2 \) with vanishing mean, \( \mathbf{n}_{S^2} \) is the unit outward normal vector field of \( S^2 \), and \( \mathbf{a} \cdot \mathbf{b} \) and \( \mathbf{a} \times \mathbf{b} \) are the inner and vector products of \( \mathbf{a}, \mathbf{b} \in \mathbb{R}^3 \). Note that the zeroth order term \( 2\nu \omega \) appears in (1) since we take the viscous them in the Navier–Stokes equations for the velocity field \( \mathbf{u} \) as twice of the divergence of the deformation tensor for \( \mathbf{u} \) (see [6]).

Let \( Y^m_n \) with \( n \geq 0 \) and \( |m| \leq n \) be the spherical harmonics and \( \lambda_n = n(n + 1) \) the eigenvalue of \( -\Delta \) corresponding to \( Y^m_n \) with \( |m| \leq n \). For \( n \geq 1 \) and \( a \in \mathbb{R} \), the vorticity equation (1) with external force \( f = a\nu(\lambda_n - 2)Y^0_n \) has a stationary solution \( \omega_n^a = aY^0_n \).

Such a stationary flow can be seen as a spherical version of the Kolmogorov flow on the 2D flat torus and we call it the \( n \)-jet Kolmogorov type flow. In this talk, we focus on the case \( n = 2 \). The linearized equation of (1) around the two-jet Kolmogorov type flow \( \omega^2 = ac^0_0(3\cos^2 \theta - 1) \) (here \( c^0_0 \) is a constant) is of the form (after relabeling \( a \in \mathbb{R} \))

\[
\partial_t \omega = \mathcal{L}^{\nu, a} \omega = \nu A \omega - iaA \omega, \quad \omega|_{t=0} = \omega_0 \quad \text{in} \quad L^2(S^2),
\]

\[
A = \Delta + 2, \quad \Lambda = \cos \theta(-i\partial_\varphi)(I + 6\Delta^{-1}),
\tag{2}
\]

where \( \theta \) and \( \varphi \) are the colatitude and longitude.

We are interested in the behavior of a solution \( \omega(t) = e^{t\mathcal{L}^{\nu, a}} \omega_0 \) to (2) as \( \nu \to 0 \). When \( (\omega_0, Y^m_1)_{L^2(S^2)} = 0 \) for \( m = 0, \pm 1 \), a standard energy method shows that \( e^{t\mathcal{L}^{\nu, a}} \omega_0 \) decays at the rate \( O(e^{-\nu t}) \). In the case of the plane Kolmogorov flow \([1, 3, 2, 8, 9]\), however, it is shown that a solution to the linearized equation decays at a rate faster than \( O(e^{-\nu t}) \) when \( \nu \) is sufficiently small. Such a phenomenon is called the enhanced dissipation, and our aim is to study the enhanced dissipation for the solution \( e^{t\mathcal{L}^{\nu, a}} \omega_0 \) to (2).

In fact, we obtained the enhanced dissipation for \( e^{t\mathcal{L}^{\nu, a}} \omega_0 \) first without a precise decay rate in [5] and then with the decay rate \( O(e^{-\sqrt{\nu} t}) \) in [4], which is the same as in the plane case [1, 2, 8, 9]. There results themselves, however, are proved just by applications of the abstract results given by Ibrahim–Maekawa–Masmoudi [2] and of the Gearhart–Prüss type theorem shown by Wei [7]. So in this talk we would like to focus on a somewhat new idea for the spectral analysis of the perturbation operator \( \Lambda \) arising in the study of the enhanced dissipation. To apply the abstract results of [2], we need to show that \( \Lambda \)
does not have nonzero eigenvalues. In order to prove it, one typically analyzes an ODE associated with $\Lambda$ and applies the uniqueness of a (smooth) solution to the ODE to show that a solution to the eigenvalue problem identically vanishes. Such an ODE approach is used in the plane case \cite{3, 2, 9}, but in our case we encounter a difficulty due to the size of the coefficient of $\Delta^{-1}$ in $\Lambda$, and it seems to be too difficult to deal with this difficulty by the ODE approach. Instead, to overcome this difficulty, we make use of the mixing property of $\Lambda$ expressed by the recurrence relation for the spherical harmonics

$$\cos \theta Y^m_n = a^m_n Y^m_{n-1} + a^{m+1}_n Y^m_{n+1}$$

with nonnegative coefficients $a^m_n$. In the actual proof, we use (3), a Hardy type inequality on $S^2$, and $\lambda_n \to \infty$ as $n \to \infty$ to show that the high frequency part (with respect to the index $n$ in the expansion by $Y^m_n$) of a solution to the eigenvalue problem vanishes, and then apply (3) again to find that the low frequency part also vanishes.

Vortex reconnection and a finite-time singularity of the Navier-Stokes equations
Yoshifumi Kimura
Graduate School of Mathematics, Nagoya University
Furo-cho, Chikusa-ku, Nagoya 464-8602, JAPAN
kimura@math.nagoya-u.ac.jp

As a fundamental process in both classical and quantum turbulence, vortex reconnection has intensively been studied over recent decades. Recently we have developed an analytical model of vortex reconnection challenging to study the finite singularity problem for the Navier-Stokes equations [1],[2]. In this model, two circular vortex rings of circulation \( \pm \Gamma \) and radius \( R = 1/\kappa \) are symmetrically placed on two planes inclined to the plane \( x = 0 \) at angles \( \pm \alpha \). Under an assumption that the vortex Reynolds number, \( R_\Gamma = \Gamma/\nu \), is very large, we have derived a nonlinear dynamical system for the local behavior near the points of closest approach of the vortices (tipping points). Careful numerical investigation of the dynamical system reveals that the magnitude of vorticity could take any large value for small viscosity but remains finite since the minimum core radius never becomes zero.

In this talk, the analytic model will be illustrated after a brief review of the problem and some preliminary numerical model [3] are presented. The assumptions for the analysis are far beyond the ones that the current DNS could attain, but we try to compare the results of the analytic model and the DNS and other numerical simulations. Finally some new development of the problem will be introduced [4].

Fast rotation limit for the incompressible Navier-Stokes equations in a 3D layer
Ryo Takada
Faculty of Mathematics, Kyushu University
takada@math.kyushu-u.ac.jp

Let $\mathbb{D} := \mathbb{R}^2 \times \mathbb{T}$ be a three-dimensional layer. Here, $\mathbb{T} = \mathbb{R}/\mathbb{Z} \simeq [0, 1]$ is the one-dimensional torus, and the point of $\mathbb{D}$ is denoted by $(x, z)$ with the horizontal variable $x = (x_1, x_2) \in \mathbb{R}^2$ and the vertical variable $z \in \mathbb{T}$.

In this talk, we consider the initial value problem for the rotating Navier-Stokes equations, describing the motion of incompressible viscous fluids around the rotating vector field $\Omega/2(-x_2, x_1, 0)$ in $\mathbb{D}$:

$$\begin{cases}
\partial_t u - \Delta u + \Omega(c_3 \times u) + (u \cdot \nabla)u + \nabla p = 0 & t > 0, (x, z) \in \mathbb{D}, \\
\nabla \cdot u = 0 & t \geq 0, (x, z) \in \mathbb{D}, \\
u(0, x, z) = u_0(x, z) & (x, z) \in \mathbb{D}.
\end{cases}$$

(1)

Here, $u = u(t, x, z) = (u_1(t, x, z), u_2(t, x, z), u_3(t, x, z))$ and $p = p(t, x, z)$ denote the unknown velocity field and the unknown pressure, respectively, while $u_0 = u_0(x, z) = (u_{0,1}(x, z), u_{0,2}(x, z), u_{0,3}(x, z))$ denotes the initial velocity field. The constant $\Omega \in \mathbb{R}$ represents the rotating speed around the vertical unit vector $c_3 = (0, 0, 1)$.

The main purpose of this talk is to prove the unique existence of global in time solutions to (1) for the initial data in scaling critical spaces, and study the asymptotics of solutions when the rotating speed $|\Omega|$ tends to infinity.

Before stating our results, we review the known results on the global existence of solutions to (1). In the whole space $\mathbb{R}^3$, Chemin, Desjardins, Gallagher and Grenier [1, 2] proved that for given initial velocity $u_0 = v_0 + w_0 \in L^2(\mathbb{R}^3)^3 + \dot{H}^{1/2}(\mathbb{R}^3)^3$, there exists a positive parameter $\Omega_0 = \Omega_0(u_0)$ such that for every $\Omega \in \mathbb{R}$ with $|\Omega| > \Omega_0$ the rotating Navier-Stokes equations (1) possesses a unique global solution. Furthermore, they [1, 2] showed that the global solution to (1) converges to that of the 2D Navier-Stokes equations with the initial data $v_0$ in the local in time norm $L^2_{\text{loc}}(0, \infty; L^q(\mathbb{R}^3))$ for $2 < q < 6$ as $|\Omega| \to \infty$. In the 3D infinite layer $\mathbb{D}$, Gallay and Roussier-Michon [3] proved the global existence and the long-time asymptotics of infinite-energy solutions to (1) for large $|\Omega|$. They [3] decomposed the initial data as $u_0 = \bar{u}_0 + \tilde{u}_0$ with $\tilde{u}_0(x) = \int_\mathbb{T} u_0(x, z) \, dz$ and $\bar{u}_0 = u_0 - \tilde{u}_0$, and showed that for given initial data $u_0 \in H^1_{\text{loc}}(\mathbb{D})^3$ satisfying $\tilde{u}_0 \in H^1(\mathbb{D})^3$, $\bar{u}_{0,3} \in H^1(\mathbb{R}^2)$, $\partial_1 \tilde{u}_{0,2} - \partial_2 \tilde{u}_{0,1} \in (L^1 \cap L^2)(\mathbb{R}^2)$, there exists an $\Omega_0 = \Omega_0(u_0) > 0$ such that (1) has a unique global solution $u$ provided that $|\Omega| \geq \Omega_0$. Moreover, it is shown in [3] that the global solution converges to the two-dimensional Lamb-Oseen vortex in $L^1(\mathbb{R}^2)$ as $t \to \infty$.

Following the idea in [3], we decompose the velocity fields as $u(t, x, z) = \tilde{u}(t, x) + \bar{u}(t, x, z)$, where

$$\tilde{u}(t, x) = (Qu)(t, x) := \int_\mathbb{T} u(t, x, z) \, dz$$

is the average of $u$ with respect to the vertical variable $z$, and we set $\bar{u} := (1 - Q)u$. Note that $\bar{u}$ has zero vertical average $\int_\mathbb{T} \bar{u}(t, x, z) \, dz = 0$. Similarly to the whole space $\mathbb{R}^3$ case in [1, 2], the limit equation is the 2D incompressible Navier-Stokes equations for the three-components...
velocity fields:
\[
\begin{aligned}
\partial_t u^\infty - \Delta_h u^\infty + (u^\infty_h \cdot \nabla_h) u^\infty + (\nabla_h q, 0) &= 0 & t > 0, & x \in \mathbb{R}^2, \\
\nabla_h \cdot u^\infty_h &= 0 & t \geq 0, & x \in \mathbb{R}^2, \\
\nabla_h = (\partial_1, \partial_2), \quad \Delta_h = \partial_1^2 + \partial_2^2, \quad u^\infty_h = (u^\infty_1, u^\infty_2) \quad \text{and} \quad q = q(t, x) \quad \text{is a 2D pressure.}
\end{aligned}
\]

where \( \nabla_h = (\partial_1, \partial_2), \Delta_h = \partial_1^2 + \partial_2^2, u^\infty_h = (u^\infty_1, u^\infty_2) \) and \( q = q(t, x) \) is a 2D pressure.

The main result of this talk reads as follows:

**Theorem 1.** For \( u_0 = \bar{u}_0 + \tilde{u}_0 \in L^2(\mathbb{R}^2)^3 + (1 - Q)\dot{H}^{\frac{2}{3}}(\mathbb{D})^3 \) with \( \nabla_h \cdot u_{0,h} = \nabla \cdot \tilde{u}_0 = 0 \), there exists a \( \Omega_0 = \Omega_0(\bar{u}_0, \tilde{u}_0) > 0 \) such that, for all \( \Omega \in \mathbb{R} \) with \( |\Omega| \geq \Omega_0 \), the rotating Navier-Stokes equation (1) admits a unique global solution \( u = \bar{u} + \tilde{u} \) satisfying

\[
\begin{aligned}
\bar{u} &\in C([0, \infty); L^2(\mathbb{R}^2))^3 \cap L^2(0, \infty; \dot{H}^1(\mathbb{R}^2))^3, \\
\tilde{u} &\in C([0, \infty); (1 - Q)\dot{H}^{\frac{2}{3}}(\mathbb{D}))^3 \cap L^2(0, \infty; (1 - Q)\dot{H}^{\frac{2}{3}}(\mathbb{D}))^3.
\end{aligned}
\]

Furthermore, for \( 2 < p, q < \infty \) with \( 2/p + 2/q = 1 \), there holds

\[
\lim_{|\Omega| \to \infty} \|u - u^\infty(t)\|_{L^p(0, \infty; L^q(\mathbb{D}))} = 0.
\]

Here, \( u^\infty \) is the unique global solution of the limit equation (2) with the initial data \( \bar{u}_0 \) in the class \( u^\infty \in C([0, \infty); L^2(\mathbb{R}^2))^3 \cap L^2(0, \infty; \dot{H}^1(\mathbb{R}^2))^3 \).

**Remark 1.** Let \( p, q \) satisfy \( 2 < p, q < \infty \) and \( 2/p + 2/q = 1 \). Then, by the Sobolev embeddings \( \dot{H}^{1-\frac{2}{3}}(\mathbb{R}^2) \hookrightarrow L^3(\mathbb{R}^2), \dot{H}^{\frac{2}{3}(1-\frac{2}{3})}(\mathbb{D}) \hookrightarrow L^6(\mathbb{D}) \) and the Poincaré inequality in \( \mathbb{D} \), we have the following relations:

\[
\begin{aligned}
L^\infty(0, \infty; L^2(\mathbb{R}^2)) \cap L^2(0, \infty; \dot{H}^1(\mathbb{R}^2)) &\hookrightarrow L^p(0, \infty; L^q(\mathbb{R}^2)), \\
L^\infty(0, \infty; (1 - Q)\dot{H}^{\frac{2}{3}}(\mathbb{D})) \cap L^2(0, \infty; \dot{H}^{\frac{2}{3}}(\mathbb{D})) &\hookrightarrow L^p(0, \infty; (1 - Q)L^q(\mathbb{D})).
\end{aligned}
\]

In the proof of Theorem 1, we adapt the ideas in [1, 2, 3], and decompose the solution to (1) as \( u = \bar{u} + \tilde{u} = u^\infty + (\bar{u} - u^\infty) + \lambda + (\tilde{u} - \lambda) \), where \( \lambda \) is the linear solution associated with the initial data \( u_0 \) whose Fourier transform is compactly supported in some ball. The key ingredients of the proof are the Strichartz estimates for the linear solution \( \lambda \), and the global energy estimates for the perturbations \( \bar{u} - u^\infty \) and \( \tilde{u} - \lambda \).

This talk is based on the joint work with Hiroki Ohyama (Kyushu University).
