# Notes on the $\varepsilon$ part in the $a b c$ conjecture 

(Including lower bounds on class numbers and effectivity in IUT)

Vesselin Dimitrov

October 30, 2016

This is a revised version of the slides used in the author's presentation at the workshop, following a correction from Professor Mochizuki during the discussion session about the optimal shape of [IUT IV, Th. 1.10]. The change concerns the implication about the Siegel zero. The effect of it is that the IUT papers do not imply no Siegel zero for L-functions attached to the odd Dirichlet characters $\chi \bmod q$ of $\mathbb{Q}$, but only the weaker property that no such $L$-function has a real zero $>1-\frac{c}{q^{\frac{1}{6}} \log q^{\prime}}$, with an effective (computable) constant $c>0$.
The author apologizes for misrepresenting [IUT IV, 1.10] in the original version.

## The abc conjecture (Some notation.)

On $P \in \mathbb{P}^{1}(\overline{\mathbb{Q}}) \backslash\{0,1, \infty\}$, all $\varepsilon>0$ satisfy

$$
\begin{array}{r}
h(P) \leq(1+\varepsilon)\left(\operatorname{cond}_{[0]+[1]+[\infty]}(P)+d(P)\right) \\
+O_{\varepsilon,(\ldots \mathbb{Q}(P): \mathbb{Q}] ?)}(1),
\end{array}
$$

where: $h=$ abs. logarithmic Weil height, $d(P)=$ abs. logarithmic root discriminant of the field $\mathbb{Q}(P)$,

$$
\operatorname{cond}_{[0]+[1]+[\infty]}(P):=\frac{1}{[\mathbb{Q}(P): \mathbb{Q}]} \sum_{v} \log |k(v)|
$$

over all $v \in M_{\mathbb{Q}(P)}^{\text {fin }}$ having $v(x)>0, v(1 / x)>0$ or $v(x-1)>0($ where $P=[x: 1])$.

## The abc conjecture (A comparison.)

In the case of complex function fields, McQuillan, Yamanoi and Chen have proved Vojta's " $1+\varepsilon$ " conjecture, that the analogous bound holds in $\mathbb{P}_{B}^{1} \backslash D$ for $D / B$ any (not necessarily isotrivial) divisor. This holds without a dependence on the degree.

## The abc conjecture (A comparison.)

In the case of complex function fields, McQuillan, Yamanoi and Chen have proved Vojta's " $1+\varepsilon$ " conjecture, that the analogous bound holds in $\mathbb{P}_{B}^{1} \backslash D$ for $D / B$ any (not necessarily isotrivial) divisor. This holds without a dependence on the degree.
A question: What then is the structure of the error term, in both inequalities? Should we expect the complex function field Vojta conjectures to hold with an $O(1 / \varepsilon)$, as is the expectation in the arithmetic case, and that this would be essentially optimal?

The abc conjecture, in a form suggested by IUT.

$$
\log \Theta \leq \frac{1}{l} \log \mathfrak{q} \quad ?
$$

## The abc conjecture, in a form suggested

 by IUT.$$
\log \Theta \leq \frac{1}{l} \log \mathfrak{q} \quad ?
$$

Let $E / F$ be an elliptic curve, $I \geq 5$ a prime level; $K=F(E[/])$;

## The abc conjecture, in a form suggested by IUT.

$$
\log \Theta \leq \frac{1}{l} \log \mathfrak{q} \quad ?
$$

Let $E / F$ be an elliptic curve, $I \geq 5$ a prime level; $K=F(E[/]) ; h(E / F)$ the Faltings height of $E$ over $F$; e the highest ramification index in $F / \mathbb{Q}$.

The abc conjecture, in a form suggested by IUT.

The abc conjecture, in a form suggested by IUT.
( $a b c_{\ominus}$ ) $2 h(E / F)$

The abc conjecture, in a form suggested by IUT.
$\left(a b c_{\Theta}\right) \quad 2 h(E / F) \leq \frac{[F: \mathbb{Q}]}{l} \cdot 2 h(E / F)$

The abc conjecture, in a form suggested by IUT.

$$
\begin{aligned}
\left(a b c_{\Theta}\right) & 2 h(E / F) \leq \frac{[F: \mathbb{Q}]}{l} \cdot 2 h(E / F) \\
+ & \frac{1}{[K: \mathbb{Q}]} \log \left|D_{K / \mathbb{Q}}\right|
\end{aligned}
$$

## The abc conjecture, in a form suggested by IUT.

$$
\begin{aligned}
\left(a b c_{\Theta}\right) & 2 h(E / F) \leq \frac{[F: \mathbb{Q}]}{l} \cdot 2 h(E / F) \\
+ & \frac{1}{[K: \mathbb{Q}]} \log \left|D_{K / \mathbb{Q}}\right|+E_{\mathrm{hr}}(K / \mathbb{Q})+C,
\end{aligned}
$$

where, with $e_{p / K}$ the highest ramification index of $p$ in $K$,
$E_{\mathrm{hr}}(K / \mathbb{Q})=\sum_{\substack{p \in M_{\mathbb{Q}} \\ e_{\rho / K} \geq p-1}} \log e_{p / K} \quad$ ("high ramification").

## The abc conjecture, in a form suggested by IUT.

In our case (IUT), we have:
$E_{\mathrm{hr}}(K / \mathbb{Q}) \lesssim \#\{$ primes $p \leq e l$ ramifying in $K\} \cdot \log e l$,
which by Chebyshev's theorem is $\ll e l$.
The optimal choice of $I$ then gives a square root error as $F$ ranges through number fields of a fixed degree.

## Why would I formulate the abc hypothesis

 like that?- When $h(E / F)$ is depleted at 2 and $\infty$, and under the appropriate "genericity" restrictions on initial data ( $E / F$ split semistable, $K / F$ a large extension, I prime to the orders of the $q$-parameters...), this is exactly what [IUT-IV, Thm. 1.10] amounts to.

## Why would I formulate the abc hypothesis

 like that?- This is a statement that shows explicitly the role of arithmetic ramification in the structure of the main as well as "error" terms.

## Why would I formulate the abc hypothesis

 like that?- This is a statement that shows explicitly the role of arithmetic ramification in the structure of the main as well as "error" terms.
- It suggests that a similar structure of the error term could be present in generalizations of $a b c$ (e.g. Vojta's conjectures).

## Why would I formulate the abc hypothesis

 like that?- This is a statement that shows explicitly the role of arithmetic ramification in the structure of the main as well as "error" terms.
- It suggests that a similar structure of the error term could be present in generalizations of $a b c$ (e.g. Vojta's conjectures).
- This working hypothesis $a b c_{\Theta}$, while not the uniform abc conjecture, turns out strong enough for Granville and Stark's relation banning the Landau-Siegel zero at an odd Dirichlet character of $\mathbb{Q}$.

## A note on $X(2 /) \rightarrow X(2) \cong \mathbb{P}^{1}$

This is indeed in the form of a refined Vojta conjecture in the particular case of the complete curve $X(2 /)$, which is of hyperbolic type precisely under the $I \geq 5$ assumption.

## A reformulation on the modular curve, in

 a special caseThe link between the two versions is most naturally made by taking the model $Y(2)$ of $\mathbb{P}^{1} \backslash\{0,1, \infty\}$, and noting $2 h^{\text {st }}(E) \sim \frac{1}{6} h\left(j_{E}\right) \sim h(\lambda)$.

## A reformulation on the modular curve, in

 a special caseThe link between the two versions is most naturally made by taking the model $Y(2)$ of $\mathbb{P}^{1} \backslash\{0,1, \infty\}$, and noting $2 h^{\text {st }}(E) \sim \frac{1}{6} h\left(j_{E}\right) \sim h(\lambda)$. Recall $Y(2)_{\mathbb{C}}=\mathbb{H} / \Gamma(2)$, with $\Gamma(2)$ the kernel of reduction mod 2 in the elliptic modular group $\Gamma(1)=\operatorname{PSL}(2, \mathbb{Z})$. Like any Shimura variety, $Y(2)$ comes with its distinguished "special points," giving elliptic curves with CM. A point $P \in Y(2)(F)$ is represented by an elliptic curve $E / F$ with $F$-rational 2-torsion and a labeling of its points of order two.

## Reformulation on the modular curve: a

 case of square root errorLet $\operatorname{cond}_{/ F}(P):=\frac{1}{[F: \mathbb{Q}]} \log \left|N_{F / \mathbb{Q}}\left(\mathrm{f}_{E / F}\right)\right|$ the logarithmic conductor and $h_{/ F}(P):=h(E / F)$, the Faltings height function. As before, let $d_{F}$ the logarithmic root discriminant of $F$. Then $a b c_{\Theta}$ implies a semi-uniform $a b c$ conjecture:

$$
\left.\begin{array}{r}
2 h_{/ F}(P) \leq \operatorname{cond}_{/ F}(P)+d_{F} \\
+O\left(e \sqrt{[F: \mathbb{Q}](\operatorname{cond} / F}(P)+d_{F}\right)
\end{array}\right),
$$

( $e$ a bound on the abs. ramification indices of $F$ ).

## Reformulation on the modular curve: a case of logarithmic error

Furthermore, if $E / F$ has everywhere good reduction then $2 h(E / F) \leq d_{F}+O\left(e+\log d_{F}+\log [F: \mathbb{Q}]\right)$ (absolute implied constant).

## Reformulation on the modular curve: a

 case of logarithmic errorFurthermore, if $E / F$ has everywhere good reduction then $2 h(E / F) \leq d_{F}+O\left(e+\log d_{F}+\log [F: \mathbb{Q}]\right)$ (absolute implied constant).
Why is this implied by $a b c_{\ominus}$ ? Well, if $E / F$ has everywhere good reduction then, by Néron-Ogg-Shafarevich, either $p=I$ (with $\left.\log e_{I / K} \ll \log l\right)$, or else $e_{p / K} \leq e$; hence, the $E_{\text {hr }}$ term is just $\ll e+\log l$.

## Reformulation on the modular curve: a

 case of logarithmic errorOn the other hand, in general,

$$
\operatorname{cond}(E / K)+d_{K}=\operatorname{cond}(E / F)+d_{F}+O(\log l)
$$

See Prop. 1.3 in [IUT-IV], as used in step (ii) on page 24 of loc.cit., or Prop. 14.4.6 (and its proof) in Bombieri and Gubler's Heights in Diophantine Geometry.
Now choose $/ \sim[F: \mathbb{Q}] d_{F}$ in $a b c_{\Theta}$.

## Logarithmic error

The meaning of this is that when the conductor vanishes the error term should be logarithmic, like it is in Nevanlinna's Second Main Theorem.

## Special points

Let us look at what $a b c_{\Theta}$ reads at the CM points. This is Granville and Stark's argument in the language of elliptic curves.
Consider for simplicity (and WLOG) -D a fundamental discriminant and CM points with $\operatorname{End}(E)$ the maximal order $O_{D}$ in $K_{D}:=\mathbb{Q}(\sqrt{-D})$. Then, by class field theory, $E$ is defined over $H_{D}$, the Hilbert class field. $H_{D} / K_{D}$ is unramified, hence $d_{H_{D}}=d_{K_{D}}=\log \sqrt{D}$. Take $F$ to be the ray class field $\bmod 6$ of $K_{D}$. It turns out that $E$ extends as an abelian scheme over $\operatorname{Spec} O_{F}$.

## An everywhere good reduction model

For classical CM theory gives a model

$$
Y^{2}=X^{3}-27 \gamma_{2}(\tau)^{3} X-54 \gamma_{3}(\tau)^{2}
$$

for $E_{/ \mathbb{C}}$, where $\tau \in K_{D}$, and $\gamma_{2}, \gamma_{3}$ are familiar (Weber's) modular functions for $\Gamma(6)$ satisfying $\gamma_{2}^{3}-\gamma_{3}^{2}=1728$. Shimura's reciprocity law enforces $\gamma_{2}(\tau), \gamma_{3}(\tau) \in O_{F}$, while the relation shows that this Weierstrass equation has unit discriminant. Now $F / H_{D}$ is a bounded degree extension of ramification limited to $\{2,3\}$. Hence, $d_{F}=\log \sqrt{D}+O(1)$, and $e=O(1)$.

## Special points (continued)

## Conclusion: $\quad a b c_{\Theta} \Rightarrow 2 h(E / F) \ll \log D$.

References: Thm. 5.1.2 in Schertz's Complex Multiplication, for Shimura reciprocity; the same book for Weber's functions $\gamma_{2}, \gamma_{3}$; and section 2 in Granville and Stark's paper ABC implies no "Siegel zero"..., that I am presently paraphrasing.

## $h(E / F) \ll \log D$

But
$2 h(E / F)=2 h_{\text {Fal }}^{\text {st }}(E)=\log \sqrt{D}+\frac{L^{\prime}}{L}\left(1, \chi_{D}\right)+O(1)$,
by Kronecker's limit formula!

## $h(E / F) \ll \log D$

But
$2 h(E / F)=2 h_{\mathrm{Fal}}^{\mathrm{st}}(E)=\log \sqrt{D}+\frac{L^{\prime}}{L^{\prime}}\left(1, \chi_{D}\right)+O(1)$,
by Kronecker's limit formula! The right hand side of this formula gives easily an analytic expression of the height, in this CM case, in terms of the zeros of $L\left(s, \chi_{D}\right)$ :

$$
2 h^{\mathrm{st}}(E)=\sum_{\rho} \frac{1}{1-\rho}+O(1)=\sum_{\rho} \operatorname{Re} \frac{1}{\rho}+O(1) .
$$

## The Kronecker limit formula

Here this is averaged over $\operatorname{Pic}\left(O_{D}\right)$, allowing for a purely multiplicative proof, which is elementary given the (logarithmic) equidistribution of the primes of $K_{D}$ in ideal classes:
Express both sides, up to $O(1)$, as the average of $\pi y / 3-\log y$ over the dilatations $y$ of the fractional ideals of $\mathbb{Q}(\sqrt{-D}) \subset \mathbb{C}$, and link them via the factorization into prime ideals of the product of all non-zero $O_{D}$ elements inside a disk of a growing radius (by elaborating on Selberg's proof of Dirichlet's theorem).

## $h^{\text {st }}(E) \ll \log D$ and no Siegel zero

By the formula

$$
\frac{L^{\prime}}{L}\left(1, \chi_{D}\right)+\log \sqrt{D}=\sum_{\rho} \frac{1}{1-\rho}+O(1)
$$

the no Landau-Siegel zeros conjecture amounts precisely to $\frac{L^{\prime}}{L}\left(1, \chi_{D}\right) \ll \log D$.
Hence, the $a b c_{\Theta}$ hypothesis implies no Siegel zero for the L-functions attached to odd Dirichlet characters of $\mathbb{Q}$.

## What could be said from just the $S$-depleted form of $a b c_{\Theta}$, and from [IUT IV, 1.10]?

For $S \subset M_{\mathbb{Q}}$ a finite set of places, let $h^{(S)}$ be the S-depleted (Faltings) height, devoid of all components lying over $S$, and designate as $a b c_{\Theta}^{(S)}$ the corresponding (weaker) hypothesis for this height. As noted before, Thm. 1.10 of [IUT-IV] is "essentially" $a b c_{\Theta}^{\{2, \infty\}}$. (We will return at the end with some technical indications on the meaning of "essentially.")

## Reducing to a depleted form

By Mochizuki's "arithmetic analytic continuation via Belyi correspondences" [AECGP], $a b c_{\Theta}^{(S)}$ for any $S$ yields the non-uniform (degree dependent) form of the abc conjecture:

$$
\begin{array}{r}
a b c_{\Theta}^{(S)} \Rightarrow \forall \varepsilon>0, P \in \mathbb{P}^{1}(\overline{\mathbb{Q}}) \backslash\{0,1, \infty\}, \\
h(P) \leq(1+\varepsilon) \cdot\left(d(P)+\operatorname{cond}_{[0]+[1]+[\infty]}(P)\right) \\
+O_{\varepsilon,[\mathbb{Q}(P): \mathbb{Q}],|S|}(1) .
\end{array}
$$

The proof in [AECGP] is phrased as an indirect argument, by contradiction. It turns out that this argument can be made direct and effective.

## Effectivity

The following is outlined in the ArXiv preprint [Effectivity]. (Though we shall see that we may sometimes do better, by relaxing Mochizuki's compact boundedness condition.)

Dimitrov V.: Effectivity in Mochizuki's work on the abc-conjecture, ArXiV: 1601.03572 v 1 .

## Effectivity

## Theorem

There are computable functions
$c: \mathbb{N} \times(0,1) \rightarrow(0,1), B, C: \mathbb{N} \times(0,1) \times \mathbb{N} \rightarrow \mathbb{R}$ such that the following is true.
Suppose $A: \mathbb{N} \times(0,1) \rightarrow \mathbb{R}$ is a function such that, for all $d$ and $\varepsilon$, all $E / F$ meeting $[F: \mathbb{Q}] \leq d$ and $\left|j_{E}\right|_{v} \leq B(d, \varepsilon,|S|)$ for all $v \in S$ fulfil $2 h(E / F) \leq(1+\varepsilon)\left(d_{F}+\operatorname{cond}(E / F)\right)+A(d, \varepsilon)$.
Then, for all $d$ and $\varepsilon$, all $E / F$ with $[F: \mathbb{Q}] \leq d$ fulfil

$$
\begin{array}{r}
2 h(E / F) \leq(1+\varepsilon)\left(d_{F}+\operatorname{cond}(E / F)\right) \\
+2 A\left(150 d\left\lfloor\varepsilon^{-2}\right\rfloor, c(d, \varepsilon,|S|)\right)+C(d, \varepsilon,|S|) .
\end{array}
$$

## Belyi correspondences

The involvement in IUT of the I-division field $K=F(E[/])$ of an elliptic curve, with its attendant constructions like $q=q^{1 / 2 l}$, makes inherent in the theory one particular Belyi map: the covering $f_{l}: Y(2 /) \rightarrow Y(2) \cong \mathbb{P}^{1} \backslash\{0,1, \infty\}$. We could easily formulate a version of $a b c_{\Theta}$ for an arbitrary Belyi map $f$ (then the role of $I$ is taken place by the minimum over $f^{-1}\{0,1, \infty\}$ of the ramification indices of $f$ ), but any other choice means giving up the elliptic curve, its theta functions, its associated hyperbolic orbicurves, the fundamental groups and anabelian transport - in short, everything that makes up IUT.

## Belyi correspondences: switching dessins

In [AECGP] and in [Effectivity], the dessins are changed not by morphisms but by correspondences: diagrams

with $\pi, f$ non-constant morphisms branched only on $\{0,1, \infty\}$.

## Belyi correspondences: switching dessins

$\pi$ should be a basic map having high ramification indices, say $\geq n$, at all points in $\pi^{-1}\{0,1, \infty\}$. The conceptually simplest choice is the $f_{l}: Y(2 l) \rightarrow Y(2)$ above, and from the point of view of equations and computations, the simplest choice is the function $x^{n}$ on the Fermat curve
$C_{n}: x^{n}+y^{n}=1$.

## The mechanics of a Belyi correspondence

For any diagram $\pi, f: C \rightarrow \mathbb{P}^{1}$ as before (defined over $\mathbb{Q})$, and any point $P \in \mathbb{P}^{1}(\overline{\mathbb{Q}})$ of degree $d$, take a lift $Q \in \pi^{-1}(P)$ and follow $f(Q) \in \mathbb{P}^{1}(\overline{\mathbb{Q}})$. By Riemann-Hurwitz, with an effective " $O(1)$ " in terms of equations for $C$ and $\pi$, $h_{K_{c}}(Q) \geq(1-3 / n) h(P)+O_{\pi}(1)$. By a computation of differents using Chevalley-Weil, Riemann-Hurwitz for $E=f^{*}([0]+[1]+[\infty])_{\text {red }}$ gives...

## The mechanics of a Belyi correspondence

$$
\begin{array}{r}
h_{C_{c}}(Q)=h(f(Q))-h_{E}(Q)+O_{f}(1) \\
\leq_{a b c}(1+\epsilon)\left(d(Q)+\operatorname{cond}_{E}(Q)\right)-h_{E}(Q)+O_{\epsilon, f}(1) \\
\leq(1+\epsilon) d(Q)+\epsilon h_{E}(Q)+O_{\epsilon, f}(1),
\end{array}
$$

if abc can be applied to $f(Q)$. The second term is $\ll \operatorname{deg} f h_{K_{c}}(Q)$ and so harmless if $\epsilon \ll \operatorname{deg} 1$.
The argument here goes back to Elkies and Vojta.

## "Compact boundedness"

We are left with insuring that $a b c$ is applicable to $f(Q)$. This follows from $a b c_{\Theta}^{\{2, \infty\}}$ - and hence, by additional standard arguments, from [IUT IV, 1.10], - if we arrange for the Galois orbit of $f(Q)$ to be bounded away from the cusps $[0]+[1]+[\infty]$ at the places 2 and $\infty$.

## This is constructive

The Galois orbit has size at most $d$ deg $\pi$ (view it as a random subset of cardinal $d \operatorname{deg} \pi$ in $\left.\mathbb{P}^{1}(\overline{\mathbb{Q}})\right)$, so if we just take any $2 d$ deg $\pi+1$ Belyi maps having pairwise disjoint critical loci, the pigeonhole principle implies that for all choices of $P$ of degree $d$, the Galois orbit of $Q\left(\in \pi^{-1}(P)\right)$ will be bounded away from the critical locus of one of these maps, at both places 2 and $\infty$. Then, at 2 and $\infty$, the Galois orbit of $f(Q)$ is bounded away from the cusps of $Y(2)$.

## This is constructive

Everything is completely effective, and quite easy to follow if we use the Fermat curve $x^{\prime}+y^{\prime}=1$, the $\operatorname{map} \pi=x^{\prime}$, and the standard presentation of a rational function $f$ on that curve as a uniquely determined element of

$$
\mathbb{Q}(x)+y \cdot \mathbb{Q}(x)+\cdots+y^{\prime-1} \cdot \mathbb{Q}(x) .
$$

## Disjoint critical loci

Mochizuki proves in [Noncritical Belyi maps] that the Belyi opens form a basis for Zariski topology on any curve. Another proof is presented in [Scherr Z., Zieve M.: Separated Belyi maps, Math. Res. Lett., vol. 21, 2014]. Both are effective; see also section 2 of [Effective], for the precise meaning of this. Hence we may place a computable, indeed explicit bound $N(I, d)$ for which we can ascertain $2 d l^{2}+1$ Belyi maps on $x^{\prime}+y^{\prime}=1$ having pairwise disjoint critical loci, and such that all polynomials involved in the presentations these Belyi maps have degrees and heights less than $N(I, d)$.

## Effective, but inefficient

The problem with this algorithmic procedure is that it is terribly inefficient, due to the successive compositions in Belyi's algorithm that are needed to reduce critical values from $\overline{\mathbb{Q}}$ to $\mathbb{Q}$. These make even the constant $N(4,1)$, which is the smallest non-trivial case, gigantic - on the order of 40 ! (forty factorial). Note that this is a bound on logarithmic heights. May we do better?

## Effective, but inefficient

The problem with this algorithmic procedure is that it is terribly inefficient, due to the successive compositions in Belyi's algorithm that are needed to reduce critical values from $\overline{\mathbb{Q}}$ to $\mathbb{Q}$. These make even the constant $N(4,1)$, which is the smallest non-trivial case, gigantic - on the order of 40 ! (forty factorial). Note that this is a bound on logarithmic heights. May we do better?
(Anyway this is not of much interest at the present stage. Effectivity is interesting as a theoretical point, for the proofs of Roth's and Faltings's theorems are inherently ineffective.)

## Relaxing the boundedness condition

This is not clear to me if we insist on bounding all the local heights at 2 and $\infty$ (attaining, that is, compact boundedness). The compact boundedness condition is much too expensive, for the set of all Belyi covers (being in correspondence with the open subgroups of the fundamental group of $\left.\mathbb{P}^{1} \backslash\{0,1, \infty\}\right)$ has a strong finiteness property for bounded degree, making it clear that the degrees of our requisite maps must be somewhat large (and must go to infinity as we need arbitrarily many maps to reach the $1+\varepsilon$ exponent and higher degree points).

## Relaxing the boundedness condition

However, all that is needed from "compact boundedness" is that the 2 - and $\infty$-portions of the height $h(E / F)$ are negligibly small in comparison with the global height $h(E / F)$. In certain situations, as we shall exploit next for large degree $d$, this is much easier to arrange.

Lower bounds on class numbers, from $a b c_{\Theta}^{(S)}$

We have seen already that IUT implies effective Roth and Faltings theorems. Let me focus here only on the remaining most significant theoretical implication. As we have seen, hypothesis $a b c_{\Theta}$ forbids Siegel zeros at odd characters of $\mathbb{Q}$. Does that persist with $a b c_{\Theta}^{(S)}$ and IUT?

Lower bounds on class numbers, from [IUT IV, 1.10]

The implication here is weaker, due to the Archimedean depletion of the height in IUT. However, it still leads to a strong effective implication, the point now being precisely the effectivity.

Lower bounds on class numbers, from [IUT IV, 1.10]

Theorem
[IUT IV, 1.10] implies a computable $C<\infty$ such that $\frac{L^{\prime}}{L}(1, \chi)<C q^{1 / 6} \log q$ for all odd Dirichlet characters $\chi \bmod q$. In other words, IUT theory implies an effective lower bound $h_{\mathbb{Q}(\sqrt{-D})} \gg(D / \log D)^{1 / 3}$ on the class number of the quadratic imaginary field of discriminant $-D<0$.

## Preparation for the proof: Habegger's theorem

In a recent paper
Habegger P.: Singular moduli that are algebraic units, Algebra and Number

```
Theory, vol. 9, no. }7\mathrm{ (2015),
pp. 1515-1524,
```

Philip Habegger obtained a modular analog of Siegel's finiteness theorem on integral points: For any algebraic $\alpha \in \overline{\mathbb{Q}}$, there are only finitely many CM elliptic curves $E / \overline{\mathbb{Q}}$ such that $1 /\left(j_{E}-\alpha\right) \in \overline{\mathbb{Z}}$ is an algebraic integer.

## Habegger's modular Siegel theorem

His proof has two main ingredients: Duke's ineffective hyperbolic equidistribution of CM points on the modular surface $\mathbb{H} / \Gamma(2)$ (which we shall not require), and an effective diophantine approximations result with two elliptic logarithms. The former shows that not too many conjugates of $j_{E}$ lie near $\alpha$, and the latter, that none of these conjugates is too close to $\alpha$. The second of these will suffice for us, and we shall apply it in exactly the same way as in Habegger's paper.

## Linear forms in two elliptic logarithms

We will use the diophantine approximations result of David and Hirata-Kohno, in exactly the same way that it is used by Habegger (see Lemma 6 there): Let $v$ be a place of $\overline{\mathbb{Q}}$ and $\alpha$ any fixed algebraic point. Then all conjugates $j(\tau)$ of $j_{E}$ (assuming $j(\tau) \neq \alpha)$ satisfy

$$
-\log |j(\tau)-\alpha|_{v} \leq c(\alpha) \log D
$$

where $c(\alpha)$ depends effectively on $\operatorname{deg} \alpha$ and $h(\alpha)$.

## Linear forms in two elliptic logarithms

The paper of David and Hirata-Kohno is [Linear forms in elliptic logarithms, J. Reine angew. Math. 628 (2009), pp. 37-89]. This is applied to the periods of the elliptic curve of invariant $\alpha \in \overline{\mathbb{Q}}$, using that $\tau$ is algebraic (a quadratic integer). Here the CM hypothesis is used crucially.
The relevant portions of [Habegger] here are Lemma 3, Lemma 6 and the calculation in the penultimate paragraph of the paper.

## A dessin switch

We shall work on the modular covering
$Y(10) \rightarrow Y(2)$, so that we have ramification indices
$\geq 4$ at all three cusps (meaning we may take $n=4$ in our previous discussion).
We have one Belyi map $\pi=f_{10}: X(10) \rightarrow X(2)$.
Construct a second one $\psi: X(10) \rightarrow \mathbb{P}^{1} \cong X(2)$ whose critical locus is disjoint from that of $\pi$. This can be done with an effective bound on the heights of all points in $\pi\left(f^{-1}\{0,1, \infty\}\right)$.

## A dessin switch

We have seen that there exists a number field $F / \mathbb{Q}$ of degree $[F: \mathbb{Q}] \sim h_{\mathbb{Q}(\sqrt{-D})}$ (the class number) and of bounded absolute ramification indices $(e=O(1))$, such that $d_{F}=\log \sqrt{D}+O(1)$ and $E$ has everywhere good reduction over $F$. These properties are preserved as we adjoin the 10-torsion to $F$ (because $E / F$ has everywhere good reduction), hence we may assume the 10-torsion of $E$ is rational over $F$.

## A dessin switch

Choose one of the points of order 10 and consider the associated points $P \in Y(2)(F)$ and $Q \in Y(10)(F)$. Then replace $P$ with $f(Q) \in Y(2)(F)$.
Apply now [IUT IV, 1.10] to $f(Q) \in Y(2)(F)$, with a choice of $I \asymp \max \left(\sqrt{h_{\mathbb{Q}(\sqrt{-D})} \cdot \log D},(\log D)^{2}\right)$. This choice is insured, effectively, by the arguments of [AECGP]; see the closing technical remarks for some indication.

## The comparison

[IUT IV, 1.10] gives:

$$
h^{\{2, \infty\}}(f(Q)) \ll \log D+\sqrt{h_{\mathbb{Q}(\sqrt{-D})} \cdot \log D}
$$

On the other hand, $h(f(Q)) \gg \sqrt{D} / h_{\mathbb{Q}(\sqrt{-D})}$, because the same holds for $h(P)$ by looking at the highest lying CM point (corresponding to the principal ideal class).
The implied constants here are effective.

## Applying the theorem of David and Hirata-Kohno

The following is thus sufficient to conclude. Indeed, an $O\left(D^{1 / 7}\right)$ version suffices.
Lemma: $\quad h(f(Q))-h^{\{2, \infty\}}(f(Q))=O(\log D)$, with effective implied constant.
Proof. It suffices to prove that all conjugates $Q^{\sigma}$ satisfy

$$
\log \left|j\left(f\left(Q^{\sigma}\right)\right)\right|_{v} \ll \log D
$$

for $v \in\{2, \infty\}$. This follows from applying David and Hirata-Kohno's theorem as $\alpha$ runs through the finite set $j\left(\pi\left(f^{-1}\{0,1, \infty\}\right)\right) \subset Y(1)(\overline{\mathbb{Q}})=\overline{\mathbb{Q}}$.

## Applying the theorem of David and Hirata-Kohno

Informally, the theorem of David and Hirata-Kohno shows that $Q$ is not too near to the critical locus of $f$. Then $f(Q)$ is not too near to any of the cusps 0 , 1 and $\infty$.

## Applying the theorem of David and Hirata-Kohno

Informally, the theorem of David and Hirata-Kohno shows that $Q$ is not too near to the critical locus of $f$. Then $f(Q)$ is not too near to any of the cusps 0 , 1 and $\infty$.

Since the theory of logarithmic linear forms is effective, the implied constant of this estimate is effective.

## Applying the theorem of David and Hirata-Kohno

Informally, the theorem of David and Hirata-Kohno shows that $Q$ is not too near to the critical locus of $f$. Then $f(Q)$ is not too near to any of the cusps 0 , 1 and $\infty$.

Since the theory of logarithmic linear forms is effective, the implied constant of this estimate is effective.
We note that the requisite $O\left(D^{1 / 7}\right)$ estimate is already accessible through the early literature on linear forms in two elliptic logarithms.

## Securing the choice of $I$ and $\mathbb{V}_{\text {mod }}^{\text {bad }}$

It remains to secure a choice of
$I \asymp \sqrt{h_{\mathbb{Q}(\sqrt{-D})} \cdot \log D}$ that meets the hypothesis on initial data in IUT I, applied to $f(Q) \in Y(2)(F)$, for a suitable choice of $\mathbb{V}_{\text {mod }}^{\text {bad }}$.
This is done by following [AECGP, Theorem 3.8 (b)] and [IUT IV, Cor. 2.2], replacing in loc.cit. assumptions of archimedeanly bounded moduli with the input $h_{\infty}(f(Q)) \ll \log D$ on the Archimedean part of the height, that we obtained from David and Hirata-Kohno's theorem.

## Technical notes on securing the choice of I and $\mathbb{V}_{\text {mod }}^{\text {bad }}$

We are using the new elliptic curve $E^{\prime} / F$ of $j_{E^{\prime}}=j(f(Q))$. There is a bounded degree extension $F^{\prime} / F$ over which $E^{\prime}$ has split semistable reduction. From David and Hirata-Kohno's theorem we have seen that the $\{2, \infty\}$-part of the stable Faltings height of $E^{\prime}$ satisfies $h_{\{2, \infty\}}\left(E^{\prime} / F^{\prime}\right) \leq C \cdot \log D$, with an effective constant $C<\infty$.

## Technical notes on securing the choice of I and $\mathbb{V}_{\text {mod }}^{\text {bad }}$

For each prime I consider $U_{l}$ the set of places $v \nmid 2, \infty$ of $F^{\prime}$ at which $E^{\prime}$ has a $\mathbb{G}_{m}$ reduction with I dividing the order of the $q$-parameter. If $h_{S}$ denotes the $S$-part of the height, it is easily verified that $h\left(E^{\prime} / F^{\prime}\right) \cdot \log h\left(E^{\prime} / F^{\prime}\right) \gg \sum_{l} h_{U_{l}}\left(E^{\prime} / F^{\prime}\right)$, where the $\log h$ is used as an upper bound on the maximum number of prime factors in the order of a $q$-parameter.

## Technical notes on securing the choice of I and $\mathbb{V}_{\text {mod }}^{\text {bad }}$

Noting that $\log h\left(E^{\prime} / F^{\prime}\right) \ll \log D$ (effectively), it follows from the last point that there are primes

$$
\begin{equation*}
I \asymp \max \left(\sqrt{h_{\mathbb{Q}(\sqrt{-D})} \cdot \log D},(\log D)^{2}\right) \tag{1}
\end{equation*}
$$

meeting $h_{U_{l}}\left(E^{\prime} / F^{\prime}\right) \leq h\left(E^{\prime} / F^{\prime}\right) / 4$. Assuming as we may that $h\left(E^{\prime} / F^{\prime}\right) \geq 4 C \cdot \log D$, we know also that $h_{\{2, \infty\}}\left(E^{\prime} / F^{\prime}\right) \leq h\left(E^{\prime} / F^{\prime}\right) / 4$. Hence

$$
\begin{equation*}
h_{U, \cup\{2, \infty\}}\left(E^{\prime} / F^{\prime}\right) \leq h\left(E^{\prime} / F^{\prime}\right) / 2 . \tag{2}
\end{equation*}
$$

## Technical notes on securing the choice of I and $\mathbb{V}_{\text {mod }}^{\text {bad }}$

Choose this $I$, and $\mathbb{V}_{\text {mod }}^{\text {bad }}$ the places $v \notin U_{I}, v \nmid 2, \infty$ of $F$ at which $E^{\prime}$ has a $\mathbb{G}_{m}$ reduction. By (2), the argument of [AECGP, Lemma 3.5] applies as soon as $D \gg 1$, showing that $E^{\prime} / F^{\prime}$ has no $I$-cyclic subgroup. Then the large Galois image in $\operatorname{Aut}(E[/])$ follows as in [AECGP], while (1) was the bound that we employed in the above argument.

## May we hope to work Archimedeanly?

Restricting to the case of everywhere good reduction $E / F$, everything is Archimedean and classical. The Archimedean case was once taken as a prototype for the p-adic theory. Could we hope to work directly with the Archimedean places, without having to change to $E^{\prime} / F^{\prime}$ ?

## May we hope to work Archimedeanly, and especially with CM?

The CM case as discussed before is particularly interesting; it has of course rich connections with algebraic and analytic number theory. Though of course it forbids the $\mathrm{SL}_{2}$ hypothesis on the Galois image, we could still insure a transitive Galois action on $E[/]$. And if the CM features, instead of helping, are inherently antagonistic to the anabelian methods, we may easily find a polynomial dessin switch that removes the CM while retaining integral moduli.

## A remark on the Archimedean analog of multiplicative subspaces

Since plane lattices could be more intuitive to visualize, let me mention the following regarding the Archimedean situation.

Assuming $E / F$ has everywhere good reduction, then as noted before, the Faltings height $h(E / F)$ equals, up to $O(1)$, the average of $\pi y / 3-\log y$, where $y \geq 1$ ranges over the dilatations $y=\operatorname{Im}(\tau)$, $\tau=\omega_{2} / \omega_{1}$, of the complex period lattices of the conjugate elliptic curves.

## A remark on the Archimedean analog of

 multiplicative subspacesA degree-/ isogeny $E \rightarrow E / C$ has the effect of stretching the dilatations by at most a factor of $I$, but usually, by the isogeny formula, the dilatations of $E / C$ are much smaller. The places where the dilatation becomes $/ \cdot y$ are the analogs of the primes where $C$ is a multiplicative subspace. When $\operatorname{Gal}(K / F)$ is transitive on $E[I]$, we would start with any $C$ and choose the section $\mathbb{V}: \mathbb{V}_{F} \rightarrow \mathbb{V}_{K}$ to attain the highest possible dilatation $/ \cdot y$ above each place of $F$. Since we aim for an inequality, we could as well regard $\mathbb{V}$ as a completely arbitrary choice.
